This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world’s books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that’s often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book’s long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ Make non-commercial use of the files We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ Refrain from automated querying Do not send automated queries of any sort to Google’s system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ Maintain attribution The Google “watermark” you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ Keep it legal Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can’t offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book’s appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google’s mission is to organize the world’s information and to make it universally accessible and useful. Google Book Search helps readers discover the world’s books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at [http://books.google.com/](http://books.google.com/)

THE DIFFERENTIAL DIAGNOSIS OF MALARIAL FEVERS.
BY SIMON BARUCH, M.D.,
NEW YORK.

In a recent paper 1 it was demonstrated that errors in the diagnosis of malarial fevers are frequent, in fact so constant that of the mortality ascribed to these diseases in the records of the New York Board of Health, a very large proportion may be attributed to causes other than malarial.

There is reason to apprehend that this recklessness of diagnosis is not limited to this city, but that it obtains also in other centres, where large aggregations of people are subjected to unsanitary influences, arising from overcrowding and defective systems of drainage and sewersage. These etiological elements have recently been erroneously grouped under the common head of "malaria." Thus a hydra-headed monster has arisen, which is regarded as the prime cause of every obscure case of illness, as has been shown in my last paper. Quinine is resorted to for its prevention and subual. Because of its well-known anti-malarial properties, the diseases arising from this so-called "malaria" are attacked by this remedy. But in vain. The grand weapon of the physician has lost its edge; the keen blade recoils without making an impression upon the enemy.

Why this failure? The diagnosis is plainly at fault; diseases which do not owe their origin to true malarial influences are confounded with the latter. The word malaria denotes "bad air;" therefore all.bad air produces malarial diseases, is the fallacious reasoning of the laity, and unfortunately also of many members of the profession. The term "malaria" has therefore proved to be an unhappy one, although it was intended to supplant the former incorrect designation "marsh miasm." That malarial diseases are not invariably the result of paludal emanations has been long ago demonstrated, and efforts have been made to adapt the nomenclature to the recognition of this fact. Léon Colin 4 discards the term malaria, and suggests in its stead "intoxication tellurique," thus recognizing it as a noxious influence, arising from the soil, outside of human habitations. That the latter furnish another and very different type of malaria or miasm, as different in its etiological effect as it is in its origin, is a fact which appears recently to have been disregarded, and which it is proposed to emphasize in this paper.

Before proceeding to the discussion of the differential diagnosis of malarial fever, it will be proper to define clearly what this term implies at the present time. In all works on the practice of medicine and among the majority of college teachers, this term has been restricted to a type of fevers "which are characterized by their prevalence in certain regions of the world known to produce the poison, malaria, by their periodicity and by the regular succession of the cold, hot, and sweating stage." (Bartholow)

Maclean 5 says: "Malaria, syn. marsh miasm; de-

---

1 Practise of Medicine, p. 245. 1821.
4 "The kioinio-miasmatic atmosphere (sewage, common or public) is that which is emitted from a continent or public mass of putrefying matter exposed to the solar influence," while, on the contrary, the "idio-miasmatic (above, personal or private) is that derived from a personal or private source, being produced from the filth of individuals and their habitations and diffused around them only for a small distance."
them by the authorities above cited, their management would afford the most gratifying therapeutic results which our art affords. There is no remedy in the whole range of medicine which the physician may wield with greater confidence, and to which therapeutic results may be more directly traced, than quinine in its application to true malarial fevers of every type, including the most severe.

It is important, therefore, to distinguish carefully the symptoms of diseases which simulate this class of fevers, and to eliminate all sources of error that may threaten a correct diagnosis. It is the object of this paper to group the semio-logicai elements of malarial and other fevers, intermittent and continued, in such manner as to define clearly their characteristics as well as typical features, as obtained from personal observation and from the study of practical writers on the subject.

I recognize three distinct types of malarial fevers, viz.: 1. Intermittent in their various manifestations.
2. Remittent fever.
3. Congenital or agid fever.

The latter form may be dismissed from the discussion, because it cannot be readily confounded with other types of fever, and is encountered only in localities where high temperatures develop an intense malarial toxæmia.

The symptoms of intermittent fevers are, as a rule, so pronounced and their history so clear that their diagnosis is devoid of difficulty, especially as diseases simulating them are extremely rare. Consequently, it will only be necessary in this connection to insist upon the fact that in masked cases of intermittent fever the symptoms may be obscure and possibly give rise to error. It is important in these cases to trace the history back to their earlier manifestations, and to bear in mind the tendency of all malarial fevers to recur at certain intervals or their multiples. The same period of periodicity which governs the disease while it occasions the paroxysm, continues to preside over its latent movements during the interval when no fit occurs, and thus the true periodic rate is carried on (as Graves, of Dublin, happily expresses it) "as in a clock from which the striking weight has been removed, the usual signal does not mark the termination of each certain definite portion of time."

Errors will occasionally creep into our diagnosis through inattention to the latent period of this affection. As a rule, they are readily eliminated. Among diseases which simulate severe intermittent fevers, pyæmia stands pre-eminent. Fortunately this disease is rare, but for that reason can never be of indifferent importance in any diagnosis. Dr. Charles Murchison1 says that, in his experience, the paroxysms are at times periodic and present a type of intermittent pyæmia. Sometimes they only occur after an interval of several days, at others they are quotidian, while in some instances there may be more than one paroxysm in twenty-four hours. Each paroxysm consists of a transient chilliness, or it may be a decided rigor and chattering of teeth followed by dry heat and by profuse sweating. Rigors may occur only in some paroxysms, but sweating is rarely absent. During the paroxysm the temperature may rise to 105°, 106°, or 107°. Paroxysms usually last from three to six, rarely over twelve hours. After its termination a certain amount of pyæmia may remain; the fever only remits. But very often there is a complete apyretic interval, during which the temperature may fall to 96° or 97°. Indeed, the great range of temperature is often remarkable, it may exceed 10°. Moreover, as in malarial fever, the spleen is often more or less enlarged. Billroth2 suggests that the paroxysms of fever have a similar origin to those of gout; sepiocoe disease, it seems, perhaps, from decomposing pus being poured from time to time into the blood and, under favorable circumstances, exciting rigor and fever.

"When the cause of the fever is external, as after an in-

1 London Lancet, 1879, i. 616.
2 Lectures on Surg. Pathology, ii. 55.
January 5, 1884.] THE MEDICAL RECORD.

The disease is ushered in by a chill. Not infrequently it forms the sequel of a neglected intermittent; the poison having become intensified by repetition of attacks of the latter, and continued exposure to malarial influences. The chill is not always clearly defined, as in the intermittent, but is described by the patient as a creeping sensation, running down the back and diffusing itself under the skin of the extremities. The hands and feet, nose and ears are cold; the patient's speech is interfered with by unsteadiness of the masseter muscles, which are disposed to tremulous movements whenever the mouth is opened. Chattering of teeth and other evidences of a well-pronounced chill are absent in a large proportion of cases.

Muscular soreness in various parts of the body are common; they may continue throughout the first twenty-four hours. Reaction sets in rapidly. The temperature during the cold stage does not rise so high as it does in the intermittent, but so soon as reaction is established and the extremities become warm there is a rapid elevation of temperature. The countenance becomes flushed, conjunctive injected; the eyes are brilliant, unless headache is severe, when the lids are apt to droop. There is a throbbing headache, which, from personal experience, may be likened to the beating of a hammer within the temples, and a sensation as if the frontal bone were lifted by each throb. The severity of the head-pain is deceptive, and the flush of the face of the prime cause; constipation always aggravates it.

In the more severe cases a violent delirium supervenes; not a muttering delirium with expressionless features, but a noisy raving, accompanied by great jactitation and active movement requiring restraint.

The thirst is intense from the first moment of the paroxysm. In no form of pyrexia is the thirst so violent and unappeasable. "Oh! that I could have the creek running through my throat!" is a frequent ejaculation of the fever-smiten negro. I have seen patients consume enormous quantities of cool water and still cry for more. The sweetest sound that ever greeted my ear was the gentle tinkling of ice in the water-pitcher which was approaching my bedside when suffering from this disease. This intensity of the thirst is characteristic even in mild cases of remittent fever.

The skin assumes a dingy yellowish hue immediately upon the establishment of reaction, and so continues until several days after convalescence; this is not a jaundiced hue. The conjunctival mucous lining does not show as evident a change, and the earliest sign is that of icterus when liver infarction has supervened. There are no spots at any stage of the disease upon the chest or abdomen; but an herpetic eruption around the mouth often marks the latter stages, especially during convalescence. Sudamina are occasionally seen in the declining stages, when perspiration has been profuse and continuous.

The tongue presents a characteristic appearance. It is rapidly overcast by a more or less dingy coating, sometimes brown, but more commonly leaden-hued. Its chief characteristic, however, is the rounding of the edges, and their being marked by alternate ridges and depressions, which are sometimes irregular, giving the appearance of puckering, or to the touch the edges are smooth. During the acme of the pyrexia the tongue is parched and dry; the papillae near its extremity seem to penetrate through the viscid or dry coating, which at this point is thinnest. When the fever begins to remit, the tongue softens and becomes flaccid and moist.

Among the older Southern practitioners a recognition of the appearance of puckering of the tongue is held as important for prognosis and treatment as is the thermometer to-day. So much stress was laid upon the necessity of keeping the tongue soft and moist, that mercury in small doses was repeatedly administered in order to hasten its softening, the latter being regarded as an indication that the threatening visceral inflammations were stayed in their lethal progress.

The condition of the tongue described above I regard as almost pathognomonic in all malarial fevers.

Ophthalmoscopic aid has been invoked in the diagnosis of malarial fever by Poncet. He has found frequently changes in the appearance of the fundus which may be summed up briefly as constituting a retinochorioiditis. "The papilla is prominent," says Poncet, "and of a grayish color, the peri-papillary zone of the retina is oedematous (under the membrana limitans interna fluid is found, as demonstrated by anatomical investigations); the vessels are greatly distended. There are hemorrhages in the retina, most numerous in the ciliary zone, less so in the posterior pole. The hemorrhages often show in the fundus as a bluish area, containing white blood-corpuscles. As in other organs, pigmented white blood-cells, often of considerable magnitude, are found in the vessels of the fundus." Personally the writer has no experience with ophthalmoscopic examinations in malarial fever, but it is an interesting subject and is alluded to here in order to render the description of symptoms complete.

The alimentary canal presents symptoms which are decidedly characteristic. Nausea and vomiting frequently usher in the attack, being present even during the cold stage. There is a sense of weight and constriction in the epipastic region, accompanied often by burning and extreme distress, all of which are aggravated by gratification of the fearful thirst. Great care must be taken that the fluid be imbibed only to be again ejected, clear or mixed with bile and mucus. Bile is constantly regurgitating into the stomach, and thus nausea is maintained and vomiting continues until checked by appropriate treatment.

The bowels are usually constipated; there is rarely tympany. If tenderness be present, it is found chiefly over the region of the liver, stomach, and spleen. Percussion gives an increased area of dulness over the latter organ, especially if intermittents have preceded the attack.

The urine is high-colored and scant, as in other pyrexia. It varies greatly during a period of twenty-four hours, being more abundant during the remission, and again becoming scant and more deeply colored during the exacerbation or in the event of visceral complications. The older Southern practitioners laid much stress upon this secretion as a guide to prognosis and treatment.

The temperature in remittent fever is pathognomonic, and may be regarded as more significant than in typhoid fever. In no disease, except pyrexia from pyemic processes, in which the history will clear up the diagnosis, do the encounters between heat and cold present such an interesting curve. The lowest point is usually reached during the early morning hours, or before dawn of day. Frequently the thermometer will mark 99° at 4 A.M., remaining stationary until five, and gradually rising as the day advances, until 106°, 107°, and even 108° is reached when the shadows are lengthening. The high temperature is maintained until near midnight, when it begins to drop until the remission is established about 4 or 5 A.M. Unfortunately the physician is absent during the small hours of the night, unless experience has taught him that these are the golden hours for treatment. With the decline of temperature the pulse beats with less force and frequency, the skin becomes moist, tongue soft; thirst, nausea, and vomiting abate or disappear entirely, headache ceases, jactitation subsides; the patient sinks into a quiet slumber. As if by a mysterious hand, he is transported to comfort and happiness, after having been racked by pain and thirst and vomiting the livelong day and night.

And how often does he sleep the happy hours away? The herring, having been taxed all the utmost, nestle themselves into their easy chairs, and while watching the sweet repose of the patient, themselves droop and slumber. So common is this early morning remission in true malarial remittent fever that it has been my practice for many years, whenever a serious case

---

came under my observation, to visit the patient at dawn of day. Often have I stealthily entered the sick chamber and found patient and nurses snoring in sweet accord, and often in my earlier practice have I erroneously attributed this happy condition to my fever mixtures. But woe unto the patient if these brief hours of respite glide by undisturbed, and the paroxysm of dyspeptic irritability is still unabated, now thirst has abated, and now is the time to act and act promptly. Quinine, the sheet anchor, which was rejected again and again by the stomach and bowels, and which failed to act, hypodermically administered, is kindly received by stomach and rectum during the existing truce. If the patient be not cinchonized before the day of great interview, another paroxysm occurs, which in the severe types may be fatal, in others is repeated daily, until the fever becomes continuous and the patient succumbs or recovers with organic lesions which will drag him down by gradual stages. Sad experience has taught me that the morning remission of remittent (true malarial) fever affords at once a pathognomonic symptom and a therapeutic opportunity.

In the "Transactions of the South Carolina Medical Association" for 1875, I reported a case which illustrates this point. I removed a sarcomatous tumor involving the entire left upper maxilla from a boy, sixteen years of age. Patient made good recovery, being able to visit my house thirteen years after 02/15/1864, day tabulated, from which patient recovered, from whom patient recovered under enormous doses of chloral and potassium bromide. Two days after complete abatement of all tetanic symptoms, twenty-five days after operation, he was attacked by a chill, followed by fever, developing a severe remittent which was at that time prevailing in the lower portion of Camden, S. C., where he had been brought from his more salubrious hilly home. Quinine was ordered, ten grains at 1 and 3 A.M. to forestall remission. The ignorant mother administered ten grains at 10 P.M., and the remainder on the next morning; failing thus to cinchonize patient. He succumbed to the disease despite energetic treatment. During the same season I saw two cases, one an adult, the other a child, fall victims to disobedience of instructions with reference to the administration of quinine during morning remission.

The pulse offers no special diagnostic indication; it does not differ from the pulse in many other pyrexias; being full, hard, strong, and accelerated during the exacerbation, soft and more natural in frequency and other qualities during the approach and during the existence of the remission.

The respiration is embarrassed in the cold stage; there is precordial oppression, followed when reaction occurs by acceleration. It again becomes nearly normal during the remission.

Both the pulse and respiration afford a reliable index of the approach of lethal complications, the former becoming rapid and feeble, and the latter furnishing good examples of Cheyne-Stokes breathing in many cases, on the approach of death.

I have delineated a clearly defined case of true malarial remittent fever from personal observation to serve as a guide for diagnosis. It remains to allude to that form of the disease which is not so clearly marked, and another type which is the result of improper management.

The former, mild remittent, though not marked by so high a temperature, still presents a pathognomonic excursus of three to four degrees; though not characterized by intense headache and jactitation, still shows an absence of listlessness and confusion of mind; though not marked by internal thirst, it is always noted as greater longing for cool beverages than is found with the same febrile symptoms in other diseases.

The tongue presents the characteristic appearance described above, and together with the yellow hue of skin, thermometric excursions, and morning remissions, renders the picture of a mild malarial remittent clear and distinguishable from other fevers.

The type of remittent fever which is developed when the early stages have been allowed to pass without active treatment, especially during the morning remissions, is with difficulty diagnosed from dyspeptic fevers. In the course of a week the remissions have become less distinct every day; the fall of temperature becomes less defined, while the higher points are still reached in the evening. Infarctions take place in the spleen and liver; the mucous lining of the stomach becomes congested. Great prostration of the nervous system ensues; the pulse becomes rapid and compressible, respiration accelerated, surface heat is increased, with cool extremities. The tongue becomes dry and contracted, its edges sharply defined and taut; the breath is almost insufferable in the evening; thirst is intense; vomiting and nausea not marked, unless gastritis has supervened. The bowels often become relaxed, diarrhoea following upon constipation; this is often the sequel of medication by active mercurial cathartics. The temperature ranges from 102° to 104° or 105°; a progression of morning, and retrogression of evening temperature having been established. When the case progresses unfavorably, temperature rises to 107° and higher; there is profound perspiration over the entire body; extremities gradually become more cool; face anxious and pale, with circumscribed efflorescence on cheeks; there is subsultus and picking at bedclothes, and hicchough; gradually the intellect becomes clouded; we have Cheyne-Stokes respiration, and the scene closes. This period may last from one to four weeks.

It is a notable fact that so soon as visceral infarction takes place, and the temperature indicates a more continued form of fever, these organic diseases usurp the original malady, and quinine is proportionately bereft of its specific effect.

While I recognize quinine as a specific anti-malarial remedy, I do not so regard it in the sense of a true antidote. During the early stages of the true malarial remittance its power is well-nigh miraculous, changing the aspect of the most threatening cases in the course of a few hours, so that they seem to be snatched from the very jaws of death. Just in proportion, however, as the periodical element wanes and is replaced by continuity of pyrexia, the power of quinine vanishes, and the physician now wages an unequal battle. For this reason quinine has failed to be of special service in the so-called typho-malarial fevers. Its action is rapid, decided, unquestionably in true malarial fever, so that whenever it fails to make an impression in a case of doubtful character, after cinchonisation is pronounced, the diagnosis may well be doubted. This has come to be a recognized axiom.

(The to be continued.)

AN APPARATUS FOR THE INHALATION OF CORROSIVE SUBLIMATE IN PHLEThOSIS.—Dr. E. P. Brewer, of Norwich, Conn., sends us the description of an apparatus which he has devised for applying corrosive sublimate (the most potent destroyer of the bacillus) in phlebitis. He uses oxygen as a medium for carrying this drug into the lungs. The apparatus consists of a tank holding one hundred and twenty gallons of oxygen at a pressure of one hundred and twenty-five pounds per square inch; a washbottle and a drying-bottle, such as are ordinarily used for washing and drying gases. Finally, a metal receptacle holding eight ounces and heated by a lamp. In this receptacle the gases expand a space of about 1 to 800 or 1,000, and heated. The oxygen passes through the washing- and drying-bottles, then through the hot and partially vaporized solution of corrosive sublimate. It then passes out through a rubber tube and is inhaled. Dr. Brewer is not yet prepared to report upon the practical results achieved by the use of his apparatus.
THE TREATMENT OF ORGANIC STRicture OF THE URETHRA BY ELECTROLYSIS.

BY W. H. DUKEMAN, M.D.

The decomposition of fibrous tissues by the therapeutic agent electricity—the galvanic or constant current—is no longer a disputed fact.

In our text-books on electricity we find many given experiments for the decomposition of various substances by this agent. But we fail to find anything of a simple experiment, by which any reference is made to demonstrate the utility of electrolysis in the treatment of organic stricture of the urethra, although much is said in favor of electrolysis in the successful treatment of morbid growths, tumors, chronic inflammations, etc.

In this article I desire, and will attempt, to demonstrate the principle of electrolysis on animal tissues, and will here quote the experiment given by me and reported in The Medical Record, vol. xxiii., No. 25. It is as follows: “Take a small piece of fresh beefsteak and lay it on an insulated surface. Then with the positive electrode placed under the surface of the beefsteak, and the negative electrode on its upper surface, where the decomposition can be watched, the conducting cords are now connected with the top of the battery. By close observation in a few seconds the effects of the electrolysis on the tissues will be seen to take place. By continuing the experiment for a few minutes the results will be distinctly appreciable.”

Now when we treat stricture of the urethra by electrolysis we have just such an action taking place on the fibrous tissues of which stricture is composed. Yet some of the most eminent of our profession say the treatment has failed in their hands, and denounce the operation as unsuccessful and unsatisfactory.

In my experience of twenty-eight cases, during the last two years, I have not had a single failure, and experience in operating has taught me that the following rules must be absolutely adhered to:

First, select a good galvanic battery which gives a steady, smooth, gentle, constant, current, of the strength of from five to fifteen volts. The urethral instruments used for the absorption of the stricture are bougies, made of metal and insulated with rubber, except the point, which is of a paddle-shaped form.

Having selected the necessary instruments we can proceed with the operation.

The recumbent position is the best. It is more agreeable to the patient and is to be preferred. To the positive pole a sponge electrode is attached, moistened with water and placed in the patient’s hand, or laid on the thigh. To the negative pole the insulated electrode bougie must be attached, and the instrument should always be inserted into the stricture before connections to the battery be made, so as to avoid any shock to the patient. The electrodes in position, connections are now made with one or two cells of the galvanic battery, and gradually increased to the desired strength. It is always advisable to begin the operation with a mild current and increase one cell at a time. Mild currents in the majority of cases give the best results. The bougie must be gently guided, no force should be used, and no pain should be inflicted. The electrolysis alone is to do the work. Care must be exercised to keep the bougie in line, so that the point will not deviate and make a false passage.

The operations should be repeated at intervals of from two to four weeks, as experience has taught that too frequent operations at short intervals are unsatisfactory.

If space will permit I will relate three cases to show the manner in which I operated, and the course and result of the operation on the patient.

Case I.—Mr. N. W., aged twenty-seven, a mechanic, presented himself for treatment August 18, 1882. Stricture, one inch and a half from meatus, ad-
cal sound, with a current of ten cells, passed both strictu-
tures in six minutes.

The injection was hydrolyzed with a current of four cells.

A No. 19 Van Buren conical sound passed both strictu-
tures in three minutes.

August 11th.—A No. 21 Van Buren conical sound passed
nicely into the bladder without the aid of electricity.

As the patient was also troubled with sexual neurasthen-
ia, the séances were repeated every couple of weeks for
another five months, with a No. 18 Van Buren conical sound, with
a current of only two and three cells. A No. 21 Van
Buren conical sound now passed into the bladder, and
patient was discharged.

I saw this a couple of weeks ago. He had not
been troubled with stricture since. No. 21 conical sound
passes easily into the bladder.

The cases already reported, together with twenty-eight
other cases which I have treated successfully during the
last two years, induces me to make this report in favor of
the operation; and I feel assured that if it be con-
ducted in accordance with directions above given every
operator will be rewarded with success.

November, 1883.

ON THE INTRA-VENOUS INJECTION OF SA-
LINE SOLUTIONS AS A SUBSTITUTE FOR
TRANSFUSION OF BLOOD.

By William T. Bull, M.D.,
Burmong to the Chambers Street and New York Hospitals.

The use of saline injections in Asiatic cholera in the
early part of this century demonstrated the safety of such
a procedure, and likewise its inefficiency in checking the
career of that disease. Within a few years, however,
this method has risen to the level of a life-saving meas-
ure, as a substitute for the transfusion of blood in con-
tions of acute anemia and collapse. Of nineteen pa-
tients who have been subjected to the operation, when
at the point of death, thirteen have entirely recovered;
in three death was averted, but occurred later; and in
the remainder only a temporary improvement was effectcd.

A recent essay* by Jennings, of London, has called
attention to the advantages of these injections, and an
editorial article in The Medical Record of October 20,
1883, gives a résumé of the subject, and speaks favor-
able of their employment. Several German writers have
proven by experiments on animals the power of a saline
solution to replace the blood, and demonstrated its ad-
vantages over the use of human blood for that purpose.

Following Cohnheim, who was the first to practise the
saline injection upon animals, Kronescher and San-
der (Berl. klin. Wochenschr., 1879, No. 52) experi-
enced on two dogs in the following manner: They were
bled from the carotid artery till the blood ceased to flow,
and then a saline solution consisting of water, 1 litre;
chloride of sodium, 6 grammes; sodium hydride, 0.1
gramme, warmed to 100° F., and in quantity equal in
weight to the blood removed, was introduced into the
external jugular vein. The animals recovered com-
pletely. This demonstrated the power of a saline solution
injected into the veins to preserve life threatened by
great loss of blood. Schwarz (Habilitationsschrift. Ha-
ßler's, 1881, p. 357) then made similar experiments on
animals, bleeding them two-thirds of the normal quantity
of blood, and injecting a per cent. watery solution of chloride of sodium, made slightly alkaline by the addition of two drops of sodic hydrate. The same
solution injected without bleeding proved to be harmless.

On the advantages and objections to the injection of saline solution as a substitute for the trans-
fusion of blood in acute anemia. Shortly after, Bischoff
employed this method successfully in a woman with
acute anemia from separation of the placenta.

The operation received further support from the experiments of Ott (Viehw. Archiv, Bd. xxii., 1 Helt), who tested
the injection of some dogs' blood, both pure and defibrinated, and of blood-serum alone, and whose conclusions I quote from a paper by v. Hacker, in the Wiener Med. Wochenschr., 1883,
No. 37. "At the close of his interesting work he comes
to the same conclusion as Schwarz, namely, that the
danger from loss of blood, even to two-thirds of its whole
volume, can be counteracted by the injection of saline solu-
tion, and of the instruments employed in the transfusion
of blood, pure and defibrinated, and that a saline solution,
both pure and defibrinated, and of blood-serum alone,
and whose conclusions I quote from a paper by v. Hacker,
in the Wiener Med. Wochenschr., 1883, No. 37. "At the

1 It was Gold (Truber des Tonus der Gefässe, Viehw. Archiv, 1879) who first established the vital importance of the vascular tension, i.e., the pressure of the
vessels on the walls, and in the blood circulation. The experimental observations of Wiegicius, the work of Winslow and McAvoy, and of the circulation, and v. Recklinghausen, in the last volume of the Deutsche Chir-
pologie (Handbuch der all. Pathologie des Kriiskassen u. der Ernahrung), and the view that in acute anesthesia the chief danger to life is from the diminu-
tion of the vessels with blood, the sinking of the blood-pressure, and the re-
volving cessation of circulation in the vital service-centres.

2 Transfusion: Its History, Indications, and Modes of Application. By Chas.

Mr. Coates has also reported a case of post-partum hemorrhage, in which the injection of twenty-two ounces of water at 100°F by Jenning's syphon was followed by recovery (Lancet, 1882, ii., 1110).

The "record" of this method of treatment justifies its further trial, and I hope that practitioners will be encouraged by the observations I have collected to adopt it. I have frequently heard men say, "I tried transfusion several times, but it did no good." But we all know that transfusion has saved the lives of many patients, and I believe that it would have saved the lives of many more had not men, in view of its risks and the circumstances attending it, deferred its performance till they were sure that their patients were going to die—till, in fact, they were moribund. Then the operation "did no good." Now the injection of the salt solution is safe and free from all the disadvantages of blood transfusion. We may hence urge its trial at a much earlier moment, and may expect a favorable result. It seems to me best, in the face of collapse from great loss of blood, to employ stimulants (hypodermically), warmth, and auto-transfu-
sion (by bandaging the extremities and raising the feet) for a limited time only, carefully noting the condition of the patient. If at the expiration of from fifteen to twenty minutes there was no decided improvement, I would proceed at once to inject the salt solution. In the cases of gas-poisoning I am sure that the use of the salt solution, to replace the blood drawn, accelerated the recovery, and I shall in future be disposed to bleed these patients more freely than I have hitherto done.

In order to have ready a vessel convenient for the operation, Mr. Ford, of Caswell, Hazard & Co., has made for me a tubulated bottle (graduated), with rubber tubing, to which a canula can be attached by means of a metallic coupling.

The salts are kept in a small phial. A trocar and also a blunt stylet are added, in order that one may puncture the vein with the former, or after opening it guide the canula into it on the latter instrument. An ordinary glass or metallic irrigator, or a funnel with tubing attached will do about as well. Let the solution (water, $\frac{1}{3}$ xxxi. ; chloride of sodium, $\frac{1}{3}$ jss. ; carbonate of soda, gr. xv.), warmed to $100^\circ$ F., flow from a height of two or three feet in the course of fifteen or twenty minutes. The canula should be no larger than a medium-sized aspirator needle, one-sixteenth inch in diameter; the apparatus disinfected with three per cent. solution of carbolic acid, and antiseptic precautions observed in operating. Choose the arm in which a well-distended vein can be seen at the bend of the elbow, and failing to find one secure the radial artery, and inject the fluid into its central end.

A SPLINT FOR THE TREATMENT OF DEFORMITY AT THE KNEE-JOINT DUE TO THE REFLEX MUSCULAR SPASM OF CHRONIC OSTEITIS.

BY JOHN F. RIDLON, A.M., M.D.,
ASSISTANT ORTHOPEDIC SURGEON TO ST. LUKE'S HOSPITAL, AND ASSISTANT SURGEON TO THE NEW YORK ORTHOPEDIC DISPENSARY AND HOSPITAL.

Fig. 1 is from a photograph showing the splint and key. The splint consists of two bars of annealed steel joined in an antero-posterior hinge, the action of which is regulated by a section of a toothed wheel and an endless screw worked by a key, and two pieces of sheet steel lined with flannel and chamois, and rivetted to the bars.

To fit and apply the splint, mould the pieces of sheet steel, one to the anterior surface of the thigh, and the other to the anterior surface of the leg. With the aid of a pair of monkey-wrenches bend the bars so that they will lie along the anterior surface of the thigh and leg, and arch over the knee from a point an inch or an inch and a half above the patella to the tuberosity of the tibia, about an inch away from the surface of the knee, and with the hinge directly anterior to the nominal centre of motion of the knee-joint in the lower end of the femur; then rivet on the pieces of sheet steel and sew on the lining. Half a dozen holes should have been made in each bar, and numerous small ones about the borders of the sheet-steel pieces by the instrument maker; but the holes in the sheet-steel pieces, through which the rivets pass, must be made by the surgeon at the time the brace is fitted, the rotation outward of the tibia in these cases necessitating this. The splint is then made fast to the leg by a roller bandage, as shown in Fig. 2, and extension made up to the point that is most agreeable to the patient.

It is believed by some that fixation of a joint suffering
is any reflex spasm. Ankylosis should not be feared, for it very rarely occurs—never, indeed, unless there has been excessive destruction of the bone. If it does occur, nothing that the surgeon could have done would have prevented it, for passive motion, by prolonging the inflammation, would tend to cause rather than hinder it.

107 West Fifty-fourth Street.

Reports of Hospitals.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM PEPPER, M.D., LL.D.,
PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

SACCHARINE DIABETES.

GENTLEMEN: I shall to-day call your attention to this young woman, who is thirty-three years of age, has been married about six months, and who four months ago noticed the first symptom of her disease in an increasing failure of strength. She gives a history of considerable mental distress connected with family troubles. The weakness first manifested itself in fatigue following the slightest exertion.

She has during the past few months also observed these additional symptoms: increased appetite, great thirst, harsh skin, dry mouth, loss of flesh, and excessive urination. The bowels are costive, but the menses are regular. Although the appetite is excessive, her digestion is poor.

Here is a specimen of her urine. It is of a lemon-yellow hue. She has passed during the last twenty-four hours six quarts of urine, a little under two hundred ounces. This is a portion of that passed this morning. Its specific gravity is 1.036. If it were a mixture of all that is passed during the entire day, the specific gravity would probably be about 1.031; for, as you know, the morning urine is more concentrated than that of other periods of the twenty-four hours. I boil a small quantity of Fehling's solution in a test-tube, add to it a drop of this urine, and at once there is a characteristic precipitate, due to the presence of sugar and the formation of the suboxide of copper. The last sample that was tested contained 6.6 per cent. of sugar.

This is clearly a case of saccharine diabetes. It is not every case of true saccharine diabetes in which the symptoms are so unmistakable as in this young woman's case. There is here no room for any discussion as to the diagnosis. Sometimes there is difficulty in making the diagnosis.

What are the symptoms which are most constantly present in saccharine diabetes, and which will therefore be mentioned most frequently by the patient? I think that excessive urination is, as a rule, noticed sooner than any other symptom. Next, I should say that increasing failure of flesh and strength is most likely to attract the attention of the patient. The debility of diabetes is extreme and remarkable, more marked than can be accounted for by the amount of loss of flesh, and all the more remarkable when taken in connection with the fact that the patient is taking and apparently assimilating a large quantity of solid, substantial, nutritious food. The patient usually complains of some disturbance as regards thirst and appetite, and nearly always we have dry mouth; sticky secretions; absence of sweat; harsh, dry skin; constipation of the bowels, and sooner or later some digestive derangement. These latter symptoms mark the fully developed attack, but the early symptoms are, as I have said, increased frequency of urination, increasing debility and loss of flesh, and some aberration of appetite and thirst. In this patient all these symptoms are present. I have, however, seen cases in which the quantity of urine passed was not very excessive, perhaps not more than sixty or seventy ounces in the twenty-four
hours, and in which the frequency of micturition and the amount of urine passed did not attract the attention of the patients. They complained simply of an apparently causeless loss of strength, and with this, paleness and some loss of flesh. Thus saccharine diabetes again illustrates that practical rule to which I have so often directed your attention; that in all cases of chronic disease, whatever organ prominently attracts attention, examination of the urine for albumen and sugar is an essential part of your investigation of the case. If you neglect this rule, you will not only constantly overlook cases of latent Bright's disease (which is far more common than saccharine diabetes), but you will occasionally overlook well-marked cases of so-called diabetes. I have frequently found sugar in the urine, when I have made the examination only because I was in the habit of so doing, or because I was searching for the cause of an otherwise inexplicable debility, the patient having complained of no symptom of saccharine diabetes.

While in most cases the symptoms of diabetes are present early and attract the attention of the patient, in other cases the symptoms are comparatively obscure. In these latter the symptom most frequently complained of is causeless debility, a giving out on the slightest exertion. With this debility there may be no loss of flesh. Other symptoms are distinctly referable to the nervous system. For instance, insomnia is occasionally quite troublesome. It appears in the case of patients who have before excessive urination or loss of flesh is complained of. The insomnia will be associated with debility as though the patient had simply overworked himself. I have frequently had patients come to me stating that they had been hard pressed in their business, had a great deal on their minds, that they began to run down, that they could not do their ordinary work, and that they could not sleep at night. Apparently nothing but an ordinary history of overwork; nothing at all to attract attention to the urine; but if you make it a rule to examine the urine in every case, you will frequently find in such patients incipient saccharine diabetes.

Diabetes is comparatively rare in young persons. It is also more common in males than in females, because the former are more exposed to its causes. I have, however, seen it in young children. I am disposed to say, from my observation of the disease, that the earlier diabetes occurs the more serious it is. This is especially true if the one who develops it in early life gives a history of a strong tuberculous tendency in the family, or if he has been subject to rheumatism and phthisis. The first case because the tendency to tuberculous disease, which is always present in a diabetic patient, is apt to be more prominent; and in the second case, because it is then unusually intractable.

The danger in diabetes is that the progressive failure of nutrition, the progressive wasting, may continue until the patient grows so weak that any intercurrent disease will carry him off; that when the vitality, flesh, and temperature have been reduced to a certain point, the patient will contract phthisis, which in diabetics runs a rapid, latent, fatal course.

I have not yet spoken of symptoms connected with alterations of the circulation. These sometimes appear at an early period. This patient complains of some numbness along the outside of the thighs. In many cases this is exceedingly prominent. Patients will complain of numbness, a dead feeling, a feeling of pins and needles. It may be felt about the feet and ankles, or it may involve almost the entire limb. It is sometimes sufficient to disturb sleep. This I class among the nervous symptoms of diabetes, and due to alterations of vaso-motor control over the circulation of the extremities.

The causes of diabetes.—I have hinted at hereditary tendency. In the next place we find prominent among the causes of diabetes, emotional strain and nerve exhaustion, particularly emotional strain. Diabetes not rarely appears after a period of worry, anxiety, and prostration of the nervous system. There is no question as to the importance of this influence as a cause of diabetes. I suppose that it starts from the nervous system, and from the control of the nerves over the vegetative processes of life, over the functional activity of the stomach, liver, and pancreas—those great organs which are concerned with the primary assimilation of food, with its absorption, and with the removal of its debris.

Positive lesions of the nervous system, tumors at the base of the brain, lesions of the floor of the fourth ventricle, from specific disease or from traumatic causes, producing thickening, hardening, or pressure, will give rise to a derangement of the function of the organs of the nervous system, as a result of long-continued, depressing, and exhausting influences, will produce diabetes.

Then we unquestionably find diabetes associated with diseases of the liver. You are all familiar with the glycosgenic function of the liver, and I shall not dwell upon it. This organ has an important work in connection with the passage of saccharine matters through the body, and probably with their consumption in the body; thus you can readily see that any derangement of the liver is very likely to cause saccharine diabetes. I cannot say that clinical observation has connected diabetes with any one special form of hepatic disease. We have seen it in this form in the case of patients with chronic hepatitis and congestion, with fatty accumulation and congestion from intemperance, and with other forms of disease, and have seen it pass away when the hepatic disease was relieved by proper treatment.

In the same way we have had cases of diabetes where, after death, the pancreas has been found diseased. We have seen the presence of chronic inflammation of the pancreas, with chronic catarh and the presence of calculi in the pancreatic ducts; and I have read the record of cases in which the glandular tissue appeared to have undergone degeneration. I therefore cannot say that it is associated with any one special disease of the pancreas.

Here, then, are various conditions in which diabetes may arise. It may be connected with simple functional derangement, or it may be associated with incurable organic disease.

Having traced the disease as nearly as possible to its source, we wish to make a prognosis. The following elements would influence us in making up our minds as to the probable result of the case and the probable effect of certain measures. We consider the age of the patient, the stage of the disease, and the amount of emaciation. These are more important than the amount of sugar and urine. I have seen cases where there was a considerable quantity of urine and sugar do well under treatment; while, on the other hand, I have seen cases in which the sugar and urine were not abundant fail to respond to treatment. A moderate amount of urine and sugar may be associated with rapid emaciation and prostration. I say, then, in our prognosis we should be guided by the youth of the patient, the duration of the disease, the amount of loss of flesh, and then the presence or absence of organic disease, particularly of the nervous system, liver, pancreas, and lungs, and finally, taking into account the therapeutic test, the effect of change of diet upon the saccharine state of the urine.

This brings us to the question of treatment, which I shall consider after examining the patient to see if there are any other symptoms not mentioned in the history which she brings us.

The eyeground is not impaired. The pupils are equally movable. The skin is dry. The face is glazed, pale, flabby, and marked by the teeth. There is no cough. There is no trace of jaundice. The pulse becomes rapid on rising. It is now 120 per minute. Auscultation of the heart-sounds shows that the first is deficient in the muscular element, but free from any murmur. There is no albumen in the urine, no oedema. She menstruates regularly.
I can find no evidence of organic disease. I am disposed to regard the diabetes in this case as purely the result of nervous influences—derangement of the nervous control over the functional activities of the liver and pancreas. We can, then, consider the treatment of this case without further reference to local conditions.

In diabetes there is a great loss of glucose. There is no use in giving to such patients free sugar with the idea of replacing that waste. This is, at first sight, a plausible theory, but it explodes on the first trial in practice. The more you give of sugar or starch, in any of their forms, the more you increase and the worse the patient becomes, and you recognize the fact that this drain cannot be replaced. Further, you find, if you prevent the ingestion of sugar and starch, that nearly all cases do better. You do this by giving albumen in its various forms, fatty articles, and gluten, that is, grain from which the starch has been washed; to these may be added succulent green vegetables not containing sugar or starch. The diet has to be varied according to the tastes of the individual, according to his circumstances in life, and according to the market which is accessible. Where money is plenty and the market good, you can make a very good bill of fare without allowing sugar or starch; but where you have to cater to the palate of a person, the taste must be considered and adjusted. You will often find it a matter of no little difficulty, and will often have to break your rule and allow a small quantity of starch or sugar, in order to prevent the patient from becoming thoroughly disgusted with his food.

The exclusion of sugar and starch from the food should not be abrupt, but should be made gradually. The diet of a diabetic patient should in general terms be something like this:

**Breakfast**: a cup of tea, without milk or sugar, but with a sliced lemon in it, according to the Russian fashion; a couple of soft-boiled eggs, broiled chops, beefsteak, or fish; oysters must be excluded, as the liver, which makes up the chief bulk of the oyster, contains sugar; with these may be given some vegetable, as a raw tomato, a raw onion with vinegar, and a slice of gluten bread or a couple of gluten biscuits.

**Between breakfast and dinner** a little cream, with a teaspoonful or so of old rum or whiskey.

**Dinner**: meat, green vegetables, string-beans, tomatoes, cauliflower, onion, lettuce (the latter contains a little sugar, but not enough to do any harm), and again gluten bread.

The evening meal is similar to the breakfast. All these articles are inexpensive and can be easily procured.

Having made the change in the diet, you watch carefully to see the effect upon the excretion of urine and sugar. While doing this, you should advise your patient to give no medicines. If you have confidence in the patient's intelligence, explain to him what you are going to do, and that you wish to see what effect the change of diet will have upon his disease, for upon this will be based your opinion as to the further progress of the case. If you have not confidence in the patient, and think that a prescription is necessary for its moral effect, I should let it be a mere placebo—a little colored water. I should not complicate the case by the administration of such remedies as opium, coca, bromide of potassium, ergot, and iron, until I had determined the effect of judicious regulation of the diet.

The exclusion of sugar and starch will be followed by one or three results:

1. The patient immediately gets wonderfully better; he sleeps better; urination is not so frequent; the quantity of urine goes down from perhaps 200 or 300 ounces to 80 or 70 ounces; and the sugar goes down to a mere trace. In other words, the regulation of the diet at once relieves the symptoms of diabetes. This is a most favorable effect.

2. In other cases the amount of urine may diminish, but still continue considerably above the normal quantity, perhaps one hundred and twenty ounces, the specific gravity keeps up, and it still contains a large proportion of sugar. Here is evidence of a profound alteration of the vital chemistry of the body. The body in which, although starch and sugar are cut off, still the patients will manufacture glucose in their bodies and the symptoms will continue. These patients will go down hill rapidly.

3. In a third class of cases we find that the patient cannot take the restricted diet. They become disgusted with it and are disposed to ask for a change, or make changes without your permission; or if they take the food they do not digest it but suffer from dyspepsia.

In this latter class of cases I should advise a still further change in the diet before administering any drug. I should put him on a diet of skim-milk, pure and simple, beginning, as I have repeatedly urged upon you the importance of doing, by confining the patient to bed, by employing a sufficient amount of friction to maintain the circulation of the extremities, and by giving the milk in small quantities, at short intervals, beginning with a gill every two hours, or in diabetes where there is much thirst, a gill every hour or hour and a half. The quantity should be gradually increased until the patient takes half a pint every hour, but he should not be kept in the state of starvation of diabetes, when carefully introduced, not allowing the patient to exert himself while on a small quantity of milk, and permitting a gradual return to exercise as the amount of milk is increased, is sometimes followed by wonderful results. Patients who have not done well on solid food from which starch and sugar have been excluded will immediately improve on a diet of skim-milk, although the latter does contain a certain amount of sugar.

It is evident that there are very different relations of the economy to starch and sugar, and the needs of the economy in reference to these articles vary very much in different patients. Sometimes although a patient is passing sugar, and although through the use of a very restricted diet he has cut off all saccharine substance, still you find by experiment that he does much better when allowed a little starch or sugar than when entirely deprived of them. He cannot assimilate the rest of his food without some sugar. Not only so, but in some cases you will find, although the urine is excessive in amount and contains sugar, and although when starch and sugar are cut off the urine decreases in amount and contains less sugar, still the patient's health fails and he grows worse; and it is only when you allow a mixed diet that he improves. I have seen stout, hearty-looking diabetics, when starch and sugar was excluded from their diet ceased to pass sugar in the urine, but grew thin, pale, weak, and dyspeptic; but being put on a mixed diet they grew fat, well-looking, and although sugar reappeared in the urine, enjoyed good health, attained an advanced age, and finally died from some other disease having 1.0 relation to the diabetes.

While I do not wish you to lose sight of the governing principle that starch and sugar should be excluded from the diet of the diabetic, I do not think that diet must be so hard and fast a rule, applying to every case, can be made. Each case must be studied carefully and treated according to its own indications. I say gradually reduce the quantity of starch and sugar, and watch the effect. If the patient does well and the symptoms diabetes improves, you know that you are on the right track and can push on boldly. If, however, you find that this diet does not answer, try skim-milk, and if that fails you must allow some starch or sugar.

In all cases, probably, certain drugs are desirable. They are less necessary in those cases which are benefited by diet. I have seen some cases entirely cured by the skim-milk treatment; the patient not only being cured of the symptoms diabetes, but of the disease. I have cured not a few diabetics by the use of koumis.
milk in which the sugar has, by fermentation, been converted into alcohol, water, and carbonic acid, the latter being retained. This is a useful diet and is easily made.

Drugs are most useful where change of diet produces the least effect upon the urine. We cannot, as a rule, determine the real essential lesion in any given case of diabetes, but have to address our drugs to this or that indication. Sometimes we can find through the affection as depending upon some not clearly defined alteration of the nervous control over this peculiar function of the liver, stomach, and pancreas, we can address our treatment only to these indications: 1. Building up the general health. 2. Lessening the excessive flow of urine. 3. Relieving the distress resulting from craving appetite and thirst, restlessness and sleeplessness; and 4. Relieving the dyspeptic disturbances.

You see that this is a purely symptomatical treatment and not based upon a comprehension of the essential nature of the disease. Hence you will find that during past centuries thousands of drugs have been recommended for the treatment of diabetes, and that hundreds are still recommended, but none of these are applicable to all cases.

The building up of the patient's constitution, the improvement of the tone of the nervous system, and the general condition of the functions are essential in the treatment of diabetes. These require close attention to hygiene, a careful regulation of the habits of life, the sedative, and the mind the body, removing or diminishing the depressing influences, and the use of general nutrients, iron, and cod-liver oil.

To lessen the flow of urine, a large number of drugs have been recommended. Of these, ergot, codeia, opium, iron, and bromide of potassium, in the order mentioned, may be said to rank as the most powerful and eligible. They lessen the excessive discharge of urine, and by so doing they lessen the thirst and give the patient a better chance to rest at night. Of these, those which are also sedative, as codeia and opium, do more. They act directly upon the nervous system; they control restlessness; they relieve insomnia; they relieve those distressing nervous symptoms, which are rarely present, connected with derangement of the circulation in the extremities. They relieve the craving of the stomach; they lessen the amount of urine passed, and the frequency of the calls to urinate.

Opium has cured some cases, but is, I think, less desirable than codeia. The latter is not so likely to produce the opium habit, is less constipating, and is not so apt to disturb gastric digestion. I consider it a valuable remedy in the treatment of diabetes. I have already mentioned iron, which is not incompatible with any of the drugs which I have mentioned.

Bromide of potassium has been vaunted as a cure for diabetes, but it, of course, occupies no such position. It is of use in relieving the nervous symptoms, and indirectly lessens the excessive flow of urine. In large doses it is depressing to the general nutrition, and is not well tolerated by many persons. It should be used with caution and only where it is well received.

The cure of digestive disturbances. If the use of any of the drugs which I have mentioned is attended with digestive disturbance, the latter may be better by an increased intake of food. The primary assimilation of food is a matter of the greatest importance in diabetes. I should much rather depend upon diet and the use of the mineral acids, bitter tonics, pepsin, and pancreatin to improve primary digestion and assimilation, and let all other remedies go, than to use any of them and have the gastric digestion continue feeble or deranged. In this case I shall first regulate the diet, and if necessary put her on the use of skim-milk. After noting the effect of diet, I shall place her upon the use of codeia, giving cod-liver oil at the same time. I shall give codeia in such doses as the intensity of the symptoms indicate, but it will not be given until the digestion is in good condition. I shall give one-half a dram to-day, and in one month shall show you the effect of this treatment upon her weight, general symptoms, special symptoms of the disease, the amount of urine, and the proportion of sugar which it contains.

Progress of Medical Science.

Subcutaneous Stretching of the Sciatic Nerve.—Owing to the unfavorable results obtained by operative nerve-stretching for the relief of locomotor ataxia in patients whose strength is greatly reduced, Dr. Lépine determined to try the effect of the very moderate amount of stretching produced by the subcutaneous method (Comptes Rendus de la Sociedad de Biologie, No. 10, 1883). This method consists in strongly flexing the thigh while the knee is retained in full extension. The immediate effects of the procedure are a slight temporary loss of sensibility in the sole of the foot and an elevation of temperature in the leg of a fraction of a degree lasting for a few hours. The curative effect is very doubtful. The most that Dr. Lépine was able to say was that the procedure could do no harm.

In the Annali Universali di Med. e Chir., Part I, 1883, Dr. Fiorani relates a case of rebellious sciatica cured by this method. The patient, a woman forty-nine years of age, had suffered for five months from a very severe sciatica. She was under the care of a rheumatic origin for which she had resisted the most varied treatment. Upon admission to hospital the patient was unable to walk, and complained of excruciating pains following the course of the right sciatic nerve, which allowed her no rest day or night. The first attempt at stretching of the nerve was made while the patient lay in bed, but full flexion of the thigh could not be made, owing to the striking of the foot against the head-board. Nevertheless, considerable improvement followed, but lasted only two days. The next attempt was made upon the operating table while the patient was under the influence of an anesthetic. As the heel was brought up to a level with the head a cracking sound was heard as if something were tearing. The leg was extended thus in a state of suspension. After the operation the sciatic pains had entirely disappeared, but the patient had a painful sensation along the posterior part of the thigh, and soon an ecchymosis appeared at the flexure of the knee, extending above and below for some distance. This passed away under appropriate treatment, and in ten days the patient left the hospital, complaining only of a slight pain, increased by locomotion. This also disappeared in the course of time, and at the end of two months the patient was entirely free from pain.

Some of the Toxic Effects of Salicylic Acid.—Dr. Max Baruch relates in the Berliner Klinische Wochenschrift, No. 23, 1883, the case of a lady for whom, on account of slight arthritic pains of a subacute character and unaccompanied with fever, salicylate of soda in doses of fifteen grains every two hours was ordered. Shortly after taking the second dose she had ringing in the ears, dizziness of vision, as if a veil were before the eyes, and a tired feeling, and soon was seized with a very severe chill lasting for an hour and a half, during which the temperature rose to nearly 106° in the axilla. After the chill the temperature fell one or two degrees, and about an hour later the patient broke out into a profuse perspiration. During this stage, lasting six or eight hours, the
temperature gradually fell to the normal. Dr. Baruch re-
garded this attack as one of intermittent fever, the more
consequently as the patient lived in a malignant district.
The only thing about it that was not perfectly typical was
the short duration of the first and second stages. In or-
ter to satisfy himself concerning the diagnosis he withheld
quinine, waiting for the second attack, but it did not
come. About five weeks later, on account of a return
of the joint pains, salicylate of soda was again ordered in
the sanatorium after taking the late. The patient had another attack of chills and fever exactly
like the former one, except that it was, if possible, more
severe. Another case similar to this, in which, however,
the symptoms were less marked, was related to the au-
 thor about the same time. In previously reported cases
of poisoning by salicylic acid the symptoms were very
different in character, and were caused by much larger
doses of the drug. The author explains his case by the
theory that even small doses of salicylic acid may so act
upon the caloric centres as to cause a paralysis of the
temperature depressors. He does not regard the sweat-
ing as caused directly by the salicylic acid, but rather
by an inhibition of the perspiratory centres from increased
temperature.
In the Centralblatt für Klinische Medicin, No. 37,
1883, Dr. M. Loeb, remarking upon this case, states that
similar febrile paroxysms not infrequently follow upon the
hypodermic injection of morphine. He does not hold the
morphine responsible for these attacks, however, but
thinks that they are due to the presence of certain forms
of bacteria in the solution used. He relates the follow-
ing case of renal hemorrhage consecutive to the admin-
istration of salicylic acid. The patient, a man twenty-
three years of age, was suffering from acute articular
rheumatism, and took nearly half an ounce of salicylic
acid in the course of twenty-four hours. At the end of
the time the urine was found to be bloody and contained
a large amount of albumen and numerous casts and blood-
corpscles, but became normal again as soon as the drug
was discontinued. Dr. Gerhardt stated to the au-
thor that he had also observed a renal hemorrhage in
several cases following upon the exhibition of salicyl-
acid. Dr. Loeb thinks that this action of the salicylates
upon the kidneys is a retention of special toxins, owing to
the fact that the remedy has recently been recommended
very strongly as the best antipyretic in scarlet fever, a
disease in which renal irritants ought most scrupulously to be avoided.

The Treatment of Diphtheria by Blue Gum Steam.—Dr. Murray Gibbs, reports thirty-seven cases of diphtheria claimed to have been cured by saturating the atmosphere of the room in which the patient was placed with the vapor of the eucalyptus globulus. The atmosphere must be constantly loaded with steam, and the vapor of the eucalyptus is obtained by pouring boiling water on the dried leaves. To assist nature in throwing off the membrane, Dr. Gibbs uses a solution of steel and glycerine, with which he brushes the throat when the membrane is loose enough to come away
gently. Dr. Moaler, in 1879, spoke strongly of the value of eucalyptus in cases of diphtheria. —London Medical Record, November 15, 1883.

Abdominal Anurism opening into the Duodenum. —Dr. Coupland reports the case of a laborer, aged sev-
enty-two, who was admitted into Middlesex Hospital in
a state of collapse. Under stimulants and warmth he
rallied from the state of collapse, but during the first few
hours the bowels were twice opened, and on each occa-
sion some black, tarry blood was passed. There was no
recurrence of this hemorrhage until just before his death,
twelve days later. Post-mortem in Philadelphia the stom-
ach was full of a dark brownish-black fluid; the
mucous membrane was intact. The duodenum con-
tained a similar fluid distinctly blood-stained. Thrusting
forward the duodenum and head of the pancreas, a glob-
ular tumor about the size of an orange could be felt.
On laying open the duodenum, four small openings were
seen in its inner wall. The tumor and aorta were re-
moved together with the duodenum in situ. On laying
open the aorta from behind, the orifice of the sac of an
aneurism was found immediately below the origin of the
renal arteries. During life, the diagnosis between aneurism and tumor of the pancreas was hard to es-
ablish.—London Medical Record, November 15, 1883.

Primary Sarcoma of the Plurura.—Mr. R. W. Greenish (Journal of Anatomy and Physiology) records a case of primary sarcoma of the pleura in a woman, aged fifty-four. There was a high left colic of the chest was full of fluid, and the pleura was covered more or less thickly
with nodules, some sessile, some pedunculated, all pig-
mented on their surfaces, hard, and cartilaginous to the
feel, and semi-translucent on section. Under the micro-
scope they presented the appearance of alveolar sarco-
amia. He has also found a number of similar cases re-
ported by various authors. In all the growth formed a
thick layer of cartilaginous hardness one to several centi-
metres thick. In two cases the right side was affected,
in six the left, and in three both sides. In six cases it
was stated to have been more advanced in the costal
pleura than elsewhere. Lépine’s case was aged ten, all
the others were over thirty-five. Birch-Hirschfeld, Bienne, Eppinger and Schulz describe the growth starting from the endothelium of the lymphatics, but Greenish finds no evidence of this, and believes the cells
to be derived from the ordinary connective-tissue cells.

Three Infectious Diseases in the Same Individual.—Dr. Prior reports (Deutsche Med. Wochenschrift) a case in which three different infectious diseases oc-
curred in the same individual in the space of one month. Three children were attended on November 18th, for
well-marked scarlatina, with a temperature of 104° Fahr.,
copious eruption, and some difficulty of swallowing.
Enanthemiation began on November 21st, and proceeded
normally, only one child having slight renal symptoms,
until, on December 1st, the two younger were attacked
with rigors, headache, and malaise, and on the following
day were covered with a thick eruption of varicella.
On December 3d, in the absence of the mother, a child
from the next room, intercourse with which had been
carefully avoided, became affected, in the evening of the
next day, the women was placed lying with the children, and showed signs of measles next day.
The first patients were now carefully watched, and on
December 15th the temperature was found to be raised,
with photophobia and slight coryza; on the 19th the
eruption of morbilli appeared. Its course was pro-
tracted, and caused some anxiety; but, finally, the
children recovered. The cases show how the two poi-
sions of scarlatina and varicella may be in the organism
at the same time, and how measles may be conveyed by
a two hours’ intercourse in the prodromal stage, while
the crusts of varicella are still present, the measles show-
ing itself as soon as ten days later.

Transmission of Yellow Fever by Mosquitoes. —At the conclusion of a long article on the nature and pathogeny of yellow fever (Cronica Medico-quirurgica de la Habana, No. 4, 1883) Dr. Carlos Finlay maintains that it may be communicated from one individual to an-
other through the agency of mosquitos, as is to be seen
under the microscope spores and filaments of a particu-
lar nature on the sting of one of these insects that had
just bitten a patient suffering from yellow fever, and
thinks that the germ may undoubtedly be introduced
into a healthy individual by the bite of a mosquito. He
recalls the fact that these insects were remarkably nu-
merous this winter, and that at the height of the fever
epidemic in 1797, and states also that the same conditions of temperature are necessary for the life
of the mosquito as for the existence and spread of yellow
fever.
THE MEDICAL RECORD:

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY
WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, January 5, 1884.

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.

The marked attention which has recently been devoted to the subject of "puerperal fever, and the management of childbed," would indicate that obstetricians are anxiously seeking the solution of the problem, how to reduce puerperal mortality.

In our city societies the theme has certainly been prolific in the production of essays and discussions. Drs. Tausky, Wylie, and Garrigues before the County Medical Society, and Drs. Thomas and Partridge in the Academy, have given the profession ample opportunity for discussion. In view of the fact that we are promised another debate in February, it may be profitable to review the work already done and, so to speak, take our bearings.

Up to the present time the chief points in the etiology and pathology of the disease have been but lightly touched, the authors and speakers being actuated by eagerness to grapple with the more inviting subject of treatment.

The views of Semmelweis and Hervieux, as more recently summarized by Lusk, that "puerperal fever is due, as a rule, to the septic inoculation of the wounds which result from the separation of the decidua and the passage of the child through the genital canal," have been acquiesced in almost unanimously, and thus by one grand sweep have been demolished the various theories of a disease which has been the theme of enormous volumes and endless discussions in the past. To-day we stand in the presence of an enemy whose strength we assume to have measured. There is an abiding faith in the minds of the best obstetricians that we have to deal with certain micro-organisms whose vulnerability by certain germicides will enable us to vanquish the foe.

While practically it would appear unimportant how these organisms obtain admission into the system, it would be wise to proceed more cautiously in the study of this subject, in order that scientific precision be not sacrificed to the practical advantages presented by the idea of a unity of infection.

It is to be hoped that in the discussion which is now pending at the Academy, the subject of pathology and etiology will be more fully elaborated. We would rejoice to know whether we are to regard every febrile movement not otherwise explicable, and every parametritis, as the direct outcome of septic processes, or whether we may not classify the puerperal pyrexia into infectious and non-infectious. It would also contribute vastly to the elucidation of this important subject, if clinical facts could be brought forward to establish a differential diagnosis between pure "traumatic" childbed pyrexia, arising from decomposition of coagula and tissue detritus at the placental site, and other types due to purely septic influences, enabling us to distinguish the embolic or phlebitic form of puerperal fever, from the lymphatic or phlegmonous which owe their origin and malignity to rapid multiplication of the septic poison.

The dominant idea of our essayists and their hearers appears to be that, as puerperal fever is the result of a trauma inflicted by the parturient process, the principles of modern wound treatment are applicable to its management.

Dr. Wylie desires to "treat the genital canal after labor as a punctured wound." Dr. Thomas goes even further, in viewing every parturient woman in the light of one who passes through a capital operation. Hence we observe a remarkable unanimity in the curative and prophylactic measures proposed by these gentlemen, and dwell upon with special emphasis by our "silver-tongued" gynecologist. But while the vigorous curative measures received general assent in all the discussions, it was not so with the "preventive measures." The latter were not referred to in detail by some of the speakers, and were warmly criticised by others. In this connection more light is needed.

How far shall the recommendations of the eloquent speaker at the Academy be adopted? Shall general practitioners everywhere religiously obey the instructions given, for instance, by Dr. Thomas in his "Prophylactic Measures?"

This is the question at issue now.

In the discussion of the papers of Drs. Tausky, Wylie, and Thomas, not a word of dissent was offered. In the debate upon Dr. Garrigues' paper, the first note of opposition came from a general practitioner. Dr. Baruch "offered his unqualified condemnation" of prophylactic injections during a normal puerperal period; basing his objections on his own experience before and since their adoption. He claims that in fifteen cases, in which a three per cent. vaginal injection had been used twice daily, he has observed six cases of undoubted septic fever. He formulated his objections on the following grounds: Disturbance of the puerpera twice a day must interfere with much needed rest (local and general); clots upon large vessels may be disturbed, opening avenues for auto-infection; the healing process of the traumatic surfaces in the vagina and cervix is interrupted; entrance of fluid into the uterus may produce shock, or collapse, or fever; and lastly, septic matter may be conveyed by the syringe in the hands of careless nurses into the uterus and vagina.

He claimed an entire immunity from deaths due to septic infection in nine hundred cases in which injections had been resorted to for cause only.

Dr. Garrish cited an experience of four thousand labor cases, with a mortality of two from puerperal fever, under strict cleanliness alone.

Dr. White claimed priority for Bellevue Hospital in the adoption of vaginal injections, but, as remarked by Dr.
January 5, 1884.]

THE MEDICAL RECORD.

Garrish, the great childbed mortality at Bellevue would render this priority a questionable virtue. Dr. White offered the result of two thousand cases of labor without a death from puerperal fever, in spite of the fact that among his private patients his order to use vaginal injections after the second day was "more honored in the breach than in the observance."

In the discussion of Dr. Partridge's excellent paper, Dr. Baruch presented an additional argument against prophylactic injections after normal labor by drawing an analogy between the stump after amputation and the wounded utero-vaginal surfaces after labor. He regarded it as the height of inconsistency to apply on the one hand (and correctly) the same surgical principles to both, and on the other to adopt entirely opposite measures in the execution of these principles. Rest, drainage, and antiseptic dressings are the arch upon which rests modern surgical treatment. Rest is the keystone of that arch; without drainage and absorbent antiseptic dressings, however, long rest would be impossible.

By scrupulous cleanliness and antiseptic before operation, the surgeon prepares an aseptic wound; after operation he again cleanses the wounded surface by antiseptic irrigation, introduces a drainage-tube, seals the lips of the wound and applies antiseptic absorbent dressings, with the hope that healing will be far advanced ere the latter are removed. He does not inject the stump daily unless there be decomposition or other cause within the wound. Drs. Wylie and Thomas and their followers would use all antiseptic precaution, without allowing the wounded surfaces to rest from these well-meaning efforts. Dr. Baruch would follow the example of the surgeon by using the precautionary measures recommended by these gentlemen, without injections, which he deems not only useless but harmful, and would depend upon the natural configuration of the vagina for drainage. Dr. Garrigues' plan marks a decided advance, inasmuch as he follows the cardinal principles adopted by the modern surgeon. He applies an antiseptic absorbent napkin, and "no vaginal injections are given, except in the rare cases in which the lochia become offensive. By the effective antisepsis at the entrance, precautionary injections become superfluous." Dr. Garrish has "used carbolic acid regularly for eight years, for hand instruments and for vaginal injections, twice daily during the first week," both in hospital and private practice. In spite of his antiseptic measures, at the Maternity Hospital his results were extremely unfavorable. From October, 1882, to April, 1883, 193 deliveries furnished 39 cases of inflammatory puerperal diseases. Since his adoption of the new treatment he has observed 97 deliveries with 5 cases of inflammatory puerperal disease, and 1 case of rise of temperature only. "As if by magic all trouble has disappeared." This lack of fever he can only explain by the perfectly aseptic condition of the genitals, and "in this respect it seems that our results are better than those observed elsewhere." He mentions in comparison Kehrer's less favorable, yet good results. But he fails to perceive that Kehrer is an enthusiastic advocate of injections, and himself reports five cases in which fever continued so long as injections were resorted to, and ceased upon their discontinuance.

To the unbiased mind it is clear as day that Dr. Garrish's remarkable success is due to non-interference with the traumatic utero-vaginal tract after completion of labor, rather than to the antiseptic napkin.

Clinical data must be brought to the elucidation of this subject. Thus far the advocates of prophylactic injections have brought no statistical data in support of their view, except Dr. Wylie, who reports thirty-six cases treated in Bellevue Hospital, all of which had rise of temperature, not above 102°. How such a result proves the value of his antiseptic injections is not apparent.

We await with interest the marshalling of these potent elements of logic in the forthcoming discussions. On the other hand, clinical data are not wanting to sustain the value of abstention from injections in normal conditions after labor.

In a brief report on "German Lying-in Institutions," by Dr. Lombard (Boston Medical and Surgical Journal, May 31, 1883), the statistical evidence in favor of antiseptic cleanliness is overwhelming. Before Semmelweis introduced his order for disinfection of hands, instruments, etc., with chloride of lime, the mortality from puerperal fever in Vienna averaged 6.2 per cent. in forty-five years, reaching fifteen per cent. in 1842. Since that time it has never risen above two per cent.; except from 1852 to 1857, when disinfection was abandoned and the death-rate rose to nine per cent. More recently it has been reduced to 0.75 per cent.

At Prague, owing to the improved hygienic condition of the new hospital and more rigid antiseptic precautions, the death-rate has been reduced from an average of 6.67 per cent. to an average of 0.77 per cent.; the rate being during the past two years 0.24 per cent. The treatment is simply the utmost precaution to prevent infection before, during, and after labor, iodoform and carbolized injections only being used at the lying-in period, in abnormal cases, as when decomposition of lochia, etc., indicates them. In Prague nearly the same course is pursued, "the patient is not disturbed until the fourth day," and then only if it be necessary to remove stitiches, etc.

Breisky is totally opposed to all prophylactic injections. Dr. Thomas' eloquent arraignment of the evils of uterine injections for prophylaxis is a valuable outcome of the present agitation of this subject. Intra-uterine injections for prophylaxis have been abandoned in Germany for several years, Max Rungl having shown even that an epidemic of puerperal fever was spread by them at the Charité.

If uterine injections are so pernicious as to be anathematized with so much vigor, it is reasonable to suppose that injections which are made into the wounded cavity of the vagina and upon the wounded cervix uteri, may be less harmful only in degree.

How much damage may really be done by vaginal injections is demonstrated by the experience of the general practitioner quoted above, an experience which has been verified by a canvass of opinions which we have recently made among a few gentlemen in large obstetric practice and the numerical data of which we may publish at a future time.

We hope to receive further information on this subject from discussions in the journals and societies. But we need exact data, not generalizations from memory.
This aspect of the question of prophylaxis is of extreme importance, in view of the fact, that, if a practitioner should neglect the now fashionable antiseptic vaginal injections and septic troubles ensue, blame may be attached to him. If, therefore, it can be established that all prophylactic injections are not only worthless, but frequently harmful, much discomfort, pain, and danger to puerperal women may be prevented. Thus far we find in the recent discussions cause for doubting the propriety of these injections when the puerperal process is proceeding normally.

Dr. Jewett stated, in speaking upon Dr. Partridge's paper, that while he has always been an ardent advocate of antisepsis in midwifery, his opinion of antiseptic injections after labor had been somewhat shaken by an experiment now in progress at the Long Island Hospital. Every other case was injected, and there appeared no difference in the result; abnormal temperature records occurred in both sets of cases alike.

Dr. Brown condemned the practice in vigorous language at the meeting of the Obstetric Section.

Statistical evidence, therefore, appears to be in favor of the abolition of this practice. The discussion has shown that this evidence, small as are the actual figures, is amply sustained by the fact that it is in entire accord with modern surgical principles.

Dr. Garrigues' method, although the most effective proposed in our societies, is not yet quite perfect.

Wounds and operations in mucous cavities have long been a stumbling-block to the execution of strict antisepsis, because carbolic acid and other germicides are too volatile, and their application to such surfaces is impracticable.

As an illustration we will cite Billroth's experience. From 1860 to 1880 he amputated the tongue one hundred and nineteen times, but, in spite of the greatest care, the most energetic cleansing of the parts by antiseptic syringing, etc., twenty-six cases died from septic infection. In 1880-81 he operated on the tongue eighteen times, with recovery in every instance. This grand result was obtained by packing the wound with iodoform gauze and allowing it to remain undisturbed from five to seven days. The same objections which hold against antiseptic syringing of the mouth in these cases would apply to this procedure in the vagina.

Aside from the well-known fact that the three per cent. solution (recommended by all our essayists and their followers) does not kill the spores of bacteria at all, and is therefore perfectly worthless as a germicide, the intermittent cleansing of the vagina does not furnish a useful antisepsis, but does, as in Billroth's tongue cases, serve to disturb the healing.

Ehrendorfer has advanced the preventive and curative treatment of puerperal septicæmia to the precise status of modern surgery. The greatest care is taken by antiseptics and cleanliness to prevent infection, but normal puerperae are left undisturbed. Only cases requiring manual assistance, or in which decomposition is threatened or takes place, are treated prophylactically. After abnormal labor the uterus is syringed with a two per cent. carbolized solution, a pencil of ninety to one hundred and twenty grains iodoform, made with starch and glycerine, is introduced into the uterus and renewed (after again injecting) only when offensive or purulent discharge occurs or fever ensues. The results are remarkable, because, as we opine, the cardinal principle of surgery, rest, is constantly kept in view, while antisepsis in other respects is observed.

M. CHARCOT'S CREED.

The recent election of Professor Charcot to membership in the Academy of Sciences was signaled by a banquet tendered to him by a large number of his pupils and admirers. At the close of the dinner a highly eulogistic speech was made by Dr. Bouchard, to which Charcot responded in a speech which, though brief, was a pertinent and striking one. Acknowledging the honor paid to him by those present, he referred to the very great share which his pupils had done in accomplishing the scientific work associated with his name. They had worked harmoniously and successfully together, because, he said, they had followed constantly and conscientiously the scientific principles and methods of the great masters of the French school.

Charcot represents and defends scientific clinical medicine as opposed to empiricism, to the entirely "practical" men. Perhaps he felt in his speech that he was advocating something which would arouse antagonism from this class. For he continued:

"If I believe firmly that there exists in medicine a domain which pertains entirely to the physician, which he alone can cultivate and fructify, and which must necessarily be closed to the physiologist who, systematically confined to his laboratory, disdains the instruction of the hospital wards, I no less firmly believe that the free intervention of the anatomical and physiological sciences in the affairs of medicine is an essential condition to its progress. I believe that practical medicine is not a real autonomy; that to live it must borrow; that without a constant scientific renovation it would soon become a dull routine. I think, finally, that as regards the qualities of quick-sightedness, ingenuity, and practical skill, which all have to be perfected by use, and are not bestowed in completeness by nature, these are as much needed by the pathologist as by the clinician. This, very briefly, is my credo. I have always held to it, and I must always continue to do so."

Charcot has stated most happily the relation between clinical medicine and the medical sciences. He has assured us also that for real scientific success the "practical" qualities are as much needed as for success in any other branch of work. His creed is a good one, and it has certainly been fruitful and stimulating at La Saldépitriére. It has also not only a general but a particular application. Every doctor who does not by study and observation infuse some new life into his daily work will soon find it true that clinical medicine is not a real autonomy, and that without constantly borrowing it soon loses vitality.

THE TREATMENT OF DIPHTHERIA BY CYANIDE OF MERCURY.

It is a circumstance often commented upon that the more intractable a disease is to therapeutic measures, the greater is the number of alleged specifics for its cure. Perhaps in few diseases is this exemplified better than in diphtheria. A bare enumeration of the many drugs and
modes of treatment proposed as curative of this affection would be as tiresome as it would be profitless. However, we may be allowed to briefly refer to a drug that has recently again claimed attention, and which may possibly be found worthy of a further and more extended trial.

In a communication in the *Allgemeine Medicinische Central- Zeitung* of September 22, 1883, Dr. Selldén, of Stockholm, relates his method of treatment by the cyanide of mercury. He employs a solution of $\frac{1}{10}$ grain to the ounce, of which, to older children and adults, he gives a teaspoonful every hour or half-hour day and night. The patient also gorges frequently with the solution. In cases of threatened heart-failure, he gives, in addition, some Tokay wine, and in desperate cases he adds to this a tablespoonful of oil of turpentine in a cup of milk. Great stress is laid upon the treatment during convalescence—fresh air, a nourishing diet, and strict confinement to bed being insisted upon. Of sixty-one cases of contagious diphtheria treated by this method, Dr. Selldén lost but three. Several years ago, Dr. Erichsen, of St. Petersburg, proposed the mercuric cyanide as a valuable remedy in the treatment of diphtheria, giving it in doses of $\frac{1}{10}$ to $\frac{1}{4}$ grain. Of twenty-five cases thus treated he lost three. Others who have used the same drug report favorable results, but from the small number of their cases and the absence of systematic observations, their testimony is of no great value.

---

THE CARE OF THE INSANE IN NEW YORK STATE.

Much attention has been paid by The Record to the subject of the care of the insane in this and other States. We have reason to believe that the profession and public have been led to take an interest in the subject, and that in the past few years great improvements have resulted in the direction desired. It is very evident, however, from a recent report made to the State Charities Aid Association, that the system of caring for the indigent insane, in this State at least, is still far from perfect. A large proportion of the class referred to are still boarded, and, after a fashion, treated in County asylums and poor-houses. Here, says the committee, a very unsatisfactory condition of affairs exists. Lunatics who, perhaps, might be cured or improved with proper care in State hospitals, were found cooped up in close cells like ox-stalls, as in Chenango County, or chained to strong iron rings in the wall of the yard, like wild animals, as in Genesee—the lack of suitable care-takers making this recourse to restraint necessary. In Broome County the bath-room was found in the coal cellar—six patients bathing in the same water, which was then saved to wash the clothes in, in the laundry. As a general rule, the insane in County poor-houses were kept in attics, basements, and outbuildings filthy and squalid. In Niagara County the secretary found insane patients shoeless, bareheaded, compelled to sit on the floor, and all, both men and women, under charge of a male pauper. The report recommends that poor-house insane wards and County asylums be abolished, and that all classes of insane be cared for by the State, in cottages of moderate cost on the vacant lands of the six present State insti-

---

LESION OF THE SYMPATHETIC IN THE NECK.

The comparative rarity of this affection and diagnostic difficulties attending it fully warrant us in noticing the case reported by Drs. Samuel Gee and John Abercrombie in "St. Bartholomew's Hospital Reports," vol. xviii., 1882.

The patient, a boy aged four years and seven months, presented the following curious and interesting group of symptoms: Ptosis of the right eye, and right hemiplegia; right pupil about one-half the size of the left; absent knee phenomenon. These were all of the positive symptoms when first seen. Later it was seen that the right pupil did not dilate so fully under atropine as the left. Two weeks later the leg became paralyzed also. At this time fever developed, which persisted; the temperature, however, not rising above 100°. One month after the paralysis of the left leg there were pains in the left shoulder and arm, and non-expansion of the chest, respiration being wholly diaphragmatic. A strong induced current was needed to obtain action of most of the leg muscles, though all acted fairly well to the constant current; cutaneous sensibility of the legs was diminished; movements of the legs caused priapism. About three weeks after this it was noted that both pupils responded to light, and contracted to the same size under eserine; patient could not move his legs and did not feel the prick of a pin; the sphincters acted involuntarily; the head was held carefully and a little to the left, and he did not lie on the left side as formerly. During sleep the head perspired profusely. After another week it was noted that he perspired only on the left side of the face, though both sides perspired after an injection of pilocarpine; the temperature in the right ear was three degrees higher than in the left. This state of things continued until death ensued, about ten days later.

The pathological appearances in this case were scarcely less striking than the clinical symptoms. In the upper part of the right pleural cavity were two irregularly lobulated, rounded masses, bulging into it at the apex from the vertebral column, of a yellowish-white color, spotted with purple and very soft on section. On examination of the vertebral column, a similar growth, continuous with the above, was found, apparently attached to the right side of the bodies of the lower cervical and upper dorsal vertebrae. The inferior cervical sympathetic ganglion on the right side could not be found. Within the spinal canal the growth was found on the inner aspect of the bodies of the same vertebrae on their right side only, pushing the cord forward and to the left. Here the growth was more purple than elsewhere. At this point the cord was small, was very soft throughout, and on section it was seen that the gray matter was very
pale and ill-defined. The growth proved, on microscopic examination, to be an alveolar sarcoma. Examination of the cord showed that in the cervical enlargement on one side the gray matter was healthy, on the other side there was a marked swelling of the large motor cells; in many instances neither their nuclei nor processes were visible. The most obvious changes below this region were turbescence of blood-vessels and increase of neuroglia corpuscles.

The paralysis of the extremities and the soft semi-fluctuant tumor by the side of the cervical spinous processes, lead in this case, very naturally, to the diagnosis of Potter's disease. Subsequent to death four points suggested themselves to the reporters, a consideration of which might have saved them from error: 1. The patient never complained of pain in the neck; whereas in ordinary cases of caries pain (in the earlier stages before there is displacement) is frequently a prominent symptom. The patient did not hold the head carefully until the swelling appeared in the neck. 2. The paralyzed legs were perfectly flaccid, there was no ankle-clonus, and the knee-phenomenon, instead of being excessive, was entirely absent. Thus there was no evidence that the lateral columns of the cord were affected, a circumstance which would be very strongly against the diagnosis of Potter's disease. 3. The coincidence of paralysis of the sympathetic with the signs of vertebral disease should cause doubt as to the existence of caries. 4. The character of the fever. The temperature remained steadily at 100° F. for more than a month, both morning and evening. The fever which is associated with scrofulous or tubercular affections is almost invariably of a remittent type, with evening exacerbations.

There were also other symptoms in this case pointing to lesion of the sympathetic nerve. Of these, the eye-symptoms appeared first. The ptosis and contracted pupil should have been regarded as pointing very strongly to sympathetic lesion, especially when taken in connection with the unilateral perspiration, which comes on, however, at a later stage. Then, too, the increased temperature of the affected side was a very strong symptom in favor of lesion of the sympathetic. It is evident that the growth passed through the intervertebral foraminis, and thus reached the cord. It is more probable that its origin was from some of the intercostal glands, for although the alveolar sarcoma, as first described by Billroth, grows in the muscle and bone, it appears to be formed generally from lymphomatous tissue.

THE CHANGES IN THE CITY HEALTH DEPARTMENT.
At a special meeting of the City Health Board last week some important changes were made in its organization. Hereafter the Sanitary Bureau will be composed of seven divisions, with an officer at the head of each at a salary of $3,000 a year. The divisions have the following functions: 1st, Sanitary Inspection; 2d, Adulterations and Offensive Trades; 3d, Public Nuisances: Matters endangering Health upon the Streets, Special In-door Inspection; 4th, Vaccination and Disinfection; 5th, Care and Maintenance of Hospital Buildings for Contagious Diseases, Treatment and Transportation of Patients; 6th, Plumbing and Ventilation; 7th, Vital Statistics.

The practical value of the above reorganization has yet to be tested. Its first effect appears to be to cause an increase in the expenses of the department, and to furnish three lucrative positions for a son of the mayor, an ex-harbor master with no experience in health matters, and a brother of Commissioner Brennan. Some of these divisions plainly do not require the expert knowledge or skill assumed to be necessary by its elaborate organization and expensive head. Three thousand dollars is a large amount to pay for the tentative services of wandering politicians and young medical graduates. The annual expenses of the City Health Department are now $411,000, a large sum to pay for the sanitary care of one million of people. The fears expressed when Professor Chandler left the Board, that it would pass into the hands of politicians, are justly aroused again by this last "deal."

We trust that our Board, though an expensive political body, will at least continue to prove efficient in its sanitary work.

News of the Week.

THE FIRST MEETING OF THE OHIO STATE SANITARY ASSOCIATION takes place at Columbus, on February 14 and 15, 1884.

VITAL STATISTICS OF NEW YORK CITY FOR THE YEAR 1883.—The Board of Health records show the number of births to be 28,972; marriages, 11,556; deaths, 35,982. There were twenty centenarians on the death-roll. The record for 1882 was 27,321 births, 11,085 marriages, and 37,924 deaths. The decrease in the death-rate is largely due to a less amount of zymotic diseases, as shown by the following:

<table>
<thead>
<tr>
<th>Disease</th>
<th>1882</th>
<th>1883</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scarlet fever</td>
<td>6,312</td>
<td>3,820</td>
</tr>
<tr>
<td>Diphtheria</td>
<td>3,507</td>
<td>2,090</td>
</tr>
<tr>
<td>Typhoid fever</td>
<td>686</td>
<td>1,373</td>
</tr>
<tr>
<td>Typhus fever</td>
<td>207</td>
<td>71</td>
</tr>
<tr>
<td>Cerebro-spinal meningitis</td>
<td>236</td>
<td>239</td>
</tr>
<tr>
<td>Measles</td>
<td>4,637</td>
<td>3,828</td>
</tr>
<tr>
<td>Small-pox</td>
<td>708</td>
<td>26</td>
</tr>
</tbody>
</table>

The total number of deaths from all zymotic diseases was 9,252; from constitutional diseases, 7,419; from local maladies, 3,681; and from developmental disorders, 2,115. Among contagious diseases scarlet fever stands at the head of the list with 3,820 victims. Other contagious maladies follow thus: Diphtheria, 2,090; typhoid fever, 1,373; typhus, 71; cerebro-spinal meningitis, 239; measles, 3,828; small-pox, 26. There have been 1,325 deaths by violence, including 61 homicides; 17 persons came to death by blows, 14 were cut or stabbed out of existence, 1 man was kicked out of the world, 23 died from gunshot wounds, 1 of strangulation, 1 was run over by a wagon, and 1 died in trying to make a bonfire of his clothing.

The list of deaths by accidental poisoning presents great variety. Opium and laudanum have ended 5 lives; hydrazine of chloral, 2; carbolic acid and opium habit, 3 each; morphia and lead, 6 each; benzine, aconite, yellow jasmine, rye whiskey, and kerosene, 1 each.

There were 1,690 deaths from heart disease, 3,128
from pneumonia, 83 from sunstroke, 524 from apoplexy, and 1,845 of Bright's disease; 8,724 of the deaths were infants less than one year old; 10,846 between one and two years, and 17,720 between two and three years; while 5,333 persons lived to see threescore and ten. In the various public institutions there were 7,856 deaths; in houses containing less than four families, 8,743; in tenements, 18,641, and in hotels, 318.

The Cost of the Charities of New York City.—Besides the excise money New York City has appropriated for the year 1884, for charities and correction, $1,774,103; for asylums, reformatories, and charitable institutions, $1,094,740. The coroners cost us $50,000, and the Health Department $411,157.

Stabbed by a Lunatic.—The medical staff of the New York City Insane Asylum take their meals together, and are waited upon by presumably tractable lunatics. Last week, however, the doctors were all sitting at dinner, and three of the patients were waiting on them, when one of the lunatics took a carving-knife, and walking around the table behind Dr. Walsh, made three savage lances. Two of the thrusts simply went through the doctor's coat, vest, and shirt, but the third made an ugly flesh wound five inches long in his side. The wound was a painful one, but not serious. The patient was disarmed and at once confined in a cell, where he will be under constant supervision.

The Rathbone Tragedy.—There can be no question that Colonel Rathbone, who has been the centre of such a fearful domestic tragedy, is and was insane. There is a fact of curious psychological interest in the case. Colonel Rathbone was in the box with President Lincoln when Booth shot and stabbed the latter. The impression made by the event was most powerful. Now, eighteen years later, Rathbone kills his wife in exactly the same manner that he saw Booth kill Lincoln, viz., with pistol and dagger.

"Ursu-Osis."—It is said, and probably with truth, that the year never ended with so many persons made actually sick by the bearish condition of the market. Melancholia, general nervous asthenia, with occasionally sugar in the urine, seem to be the characteristic features of a condition which we may term "ursu-osis." About seventy per cent. of all railroad presidents, ironmen, and buyers on margin are now affected with it.

The Changes in the City Health Board.—The reorganization of this department has resulted in a number of changes among its officers. Colonel Emmons Clark is the secretary of the board, and Caspar Goldeman chief clerk and attorney. W. P. Prantice is attorney and counsel. Dr. Moreau Morris is chief of the first division of the Sanitary Bureau, of which Dr. Walter De Forest Day remains City Sanitary Superintendent. Dr. Cyrus Edson, formerly a Sanitary Inspector, has been made chief of the second division. Major Willard Bullard, formerly a Harbor Master, has been appointed chief of the third division. Dr. J. B. Taylor is chief of the fourth division. Dr. E. H. Janes, Assistant Sanitary Superintendent, is chief of the fifth division. J. C. Collins, a clerk in Colonel Clark's office, has been made chief of the sixth division. Dr. Day is chief of the seventh division, and Dr. John T. Nagle is in it as Deputy Registrar of Records; Inspectors Hockheimer and Cowl, in the Vaccinating Bureau, and McChesney, Lockwood, C. P. Russell, Stillwell, Roberts, and G. F. Morris, in other bureaus, have been removed, but one or more of them may be reappointed. Drs. J. F. Dunphy and G. S. Conant were appointed Inspectors in the fourth division.

The Number of Suicides in New York during the past year was 161. Seventy-eight of them were married, 43 single, 24 widowed and divorced. The list includes 134 males and 27 females. Nine of them were less than twenty years old, 30 between twenty and thirty, 44 between forty and fifty, 29 between fifty and sixty, 7 between sixty and seventy, while 5 suicides became tired of life in the eighth decade. Among the nationalities Germans come first with 70 suicides. Shooting was the favorite method of killing, since it was resorted to in 56 instances. There were 19 hangings, 15 stabbings and cuttings, 12 drownings, and 11 falls from high places. Paris green was most in demand among poisons, and 18 suicides swallowed it, 7 choosing opium.

The Number of Deaths During the Past Year from Casualties, such as volcanic eruptions, accidents, marine disasters, fires, floods, etc., is estimated to be nearly one hundred thousand.

More Medical Baronets.—The Queen has announced her intention of conferring a baronetcy upon Professor Lister. This is a well-deserved honor, and one upon which he will be universally congratulated by the medical profession. For whatever views may be taken as to the value of Listerian proper, all will concede that Lister has been one of the main causes of the antisepic era in modern surgery. A baronetcy is also to be conferred upon Dr. William Bowman, a gentleman who has long been recognized as the leading ophthalmic surgeon in England.

Death of Dr. Calvin Ellis.—Dr. Calvin Ellis, Professor of Clinical Medicine in Harvard Medical College, died on December 14th from a duodenal ulcer. Dr. Ellis was born in Boston in 1826. He graduated from Harvard University in 1846, and from the Medical School in 1849. He was appointed Professor of Clinical Medicine and Visiting Physician to the Massachusetts General Hospital in 1864. Dr. Ellis was a very earnest and conscientious teacher. He made a number of contributions to clinical medicine, and was engaged upon a work on "Symptomatology" at the time of his death.

A Case of Death from the Inhalation of Ether occurred at a clinic at Bellevue Hospital recently. The patient was a boy with apparently sound lungs and heart. He was under ether for about an hour and a half when he suddenly ceased to breathe, and all efforts at resuscitation failed.

The American Hog Again.—The French Government has again changed its policy and has decided to admit salted meats, including American pork, only after a rigid inspection thereof by experts. A sensation has been caused by some very emphatic statements made by Paul Bert, to the effect that Chicago hogs are diseased to a very large extent.
BISMARCK AND HIS MEDICAL ATTENDANT.—Bismarck has made his medical attendant, Dr. Schweninger, a "Professor" unattached. He has no lectures to deliver, students to teach, or chair to occupy, but is simply Professor of the Anatomy, Physiology, and Pathology of Bismarck.

A MEDICAL LIBRARY FOR CHICAGO.—The trustees of the Chicago Public Library have decided to found a medical department to the library. The Chicago Medical Society has voted $500 to aid in starting the library, and further subscriptions are being solicited. We congratulate the profession of Chicago upon this step, although it would have been better still if the doctors had taken hold and built up a library of their own.

REFORM IN LOUISVILLE MEDICAL COLLEGES.—Two of the Louisville medical colleges, viz., the "Kentucky School of Medicine," and the "Hospital College of Medicine," have, by mutual agreement, decided to allow only two beneficiaries per term in each college. Full rates are also to be charged after 1884. The announcement of the terms of this agreement would lead one to think that there has been a great deal of cutting in rates heretofore. Sons of physicians are still admitted at half price.

ORGANIZATION OF AN ANTHROPOLOGICAL SOCIETY.—A new Society was organized last week, called the New York Anthropological Society, with Rev. Dr. E. P. Thwing as President, and Dr. A. D. Rockwell, Secretary. The object of the Society is to study and investigate the phenomena of psycho-physiology, "the vast amount of important and unclassified data in psychology which stands in vital connection with the physical, social, and moral well-being of the community." The society is composed of medical men and others interested in scientific subjects.

THE SANITARIAN has returned to its monthly form after having been issued weekly for a year. Its present make-up is a great improvement upon the older one.

SUIT TO ANNUL THE CHARTER OF THE ECLECTIC MEDICAL COLLEGE OF THE CITY OF NEW YORK.—At the instigation of the Medical Society of the County of New York, Attorney-General Russell began last week in the Supreme Court, in the name of the people of the State, a suit for the annulment of the charter of the Eclectic Medical College of the City of New York, on the ground that the officers of the college have persistently disregarded the restrictions of its charter respecting the issuance of diplomas, and, by improperly licensing unqualified persons to act as physicians, have done injury to the public. The Eclectic Medical College was organized in 1865, and has acted under a charter granted by the Legislature in that year, and amended in 1869. Respecting the alleged abuses committed by the Eclectic Medical College, the complaint says, on information and belief, that "it has issued large numbers of the diplomas of said corporation (the college) with the signatures and alleged signatures of its President and Secretary, and attested by the seal of the corporation and the signatures and alleged signatures of a majority of the Board of Censors and Instructors in said college, which said diplomas contained no name of a supposed graduate, but did contain a blank space, to be filled up by the name of some person into whose possession it might thereafter come, and such blank diplomas so issued have been by the said corporation delivered to third parties and wholly parted with by the said officers and censors, and have been exhibited and exposed for sale and unlawfully and illegally issued and disposed of to persons not legally entitled thereto ever since the said incorporation to the date of the commencement of this action." By these methods, and in other ways, the complaint continues, the Eclectic Medical College has conferred the degree of Doctor of Medicine on numerous persons known not to be of good moral character, "persons notoriously charged with, indicted for, and convicted of crimes; persons who had not pursued the study of medicine three years under the supervision of reputable physicians; persons who had not attended two full terms of instruction in an incorporated medical institution; persons who could not read, write, or speak the English language, and persons morally and generally known to be unfit to receive said diplomas and degree." It is also charged that the trustees of the college have improperly conferred the honorary degree, _ad eundem_ degree, on persons in no sense qualified to receive it. The Attorney-General asks that the college be deprived of its absurd charter and its corporate existence be annulled. The complaint is verified by Dr. David Webster, President of the County Medical Society.

POINTS OF INTEREST IN CHOREA.—Dr. A. D. Rockwell, of this city, writes: "In a late article by Dr. H. D. Chapin on 'Points of Interest in Chorea' (Medicinal Record, November 15th), he refers to the valuable results obtained by Dr. Dana in the treatment of this disease by the method of anodal galvanization. As the method is so positively valuable in chronic forms of chorea, and yet so inadequately appreciated, I am always glad to read allusions to it for confirmation of the excellent results that follow its intelligent use. The anodal galvanization to which reference is made is, however, but an incomplete and therefore unsatisfactory form of central galvanization, first described by Dr. Beard and myself many years ago, and a special chapter has been devoted to the last three editions of our work. In the clinical portion of this work also will be found cases of chorea, illustrative of the efficacy of this and other methods of electrical treatment, and in various published articles I have further emphasized the subject and proven its curative power in choreic cases of the most unpromising character. In central galvanization the idea is to influence the central nervous system as thoroughly as may be, by the galvanic current, and to this end the anode is applied to the head and the cathode over the solar plexus. In this way the brain, spinal cord, and sympathetic can be more or less influenced, and with results, beneficial, not only in obstinate cases of chorea, but in other forms of so-called functional nervous disease. Dr. Dana, in his recent and excellent article on anodal galvanization of the brain in chorea, published in The Record, alluded to the labors and successes of a number of foreign writers in the use of this form of treatment, but unconsciously, without doubt, quite overlooked and therefore failed to mention either my own efforts or the use of Dr. Beard in the same direction. As our writings on central, which of course comprehends anodal, galvanization anedated that of all the others mentioned, constituting the first systematic treatment of the subject in its relation to chorea, and to various other diseases, I beg to offer these few lines of comment and explanation."
NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 12, 1883.

GEORGE F. SHRADY, M.D., President, in the Chair.

Dr. W. H. PORTER, presented, in behalf of a candidate, a specimen of

CIRRHOSIS OF THE LIVER, WITH CANCER OF THE STOMACH.

DR. FERGUSON presented a series of specimens illustrating

CONGENITAL ANOMALIES OF THE LIVER.

First.—Enlarged right lobe, frequently at the expense of the left.

Second.—Enlargement of the left lobe, at the expense of the right lobe in some cases.

Third.—A liver having only one lobe, the organ being nearly a complete hemisphere.

Fourth.—A liver with one large lobe and several small nodules [four in the specimen presented] attached to the under surface.

Fifth.—Livers which were divided into a very large number of lobes, sixteen to twenty in one specimen, and a larger number in another.

Dr. J. C. PETERS recalled one case, that of a young girl who had congenital enlargement of the right lobe of the liver, and was apparently perfectly healthy. Her mother had suffered from intermittent fever during her pregnancy, and Dr. Dewitt, who saw the case, was positively of the opinion that the condition of the child's liver was due to the malaria from which the mother suffered before childbirth. The condition has persisted, and the girl (now a young woman) still has a large right lobe of the liver, but is in excellent health. There was no enlargement of the spleen.

DR. F. FERGUSON also presented specimens illustrating

CHRONIC DIFFUSE NEPHRITIS—ACUTE ENDOCARDITIS, removed from the body of a woman twenty-two years of age, a native of the United States, married, and a housewife by occupation. She was brought to the House of Relief November 27, 1883, with the following history: She had been acutely ill for weeks with severe pain in the chest, dyspnea, and vomiting three hours previous to her admission. She had been a patient for some time (how long she could not state) and treated in a hospital for dysentery. On admission her face was cyanosed and she complained of sharp pain in the chest. There was a loud blowing murmur over the base of the heart transmitted into the carotids. The cardiac action was masked by the dyspnea. Both the cardiac action and respiration were 26 per minute, and synchronous. She constantly failed, and died seventeen hours after admission.

The autopsy was made twenty-four hours after death. There was edema of the legs below the knees. The peritoneum contained twelve ounces of serum; there was no evidence of peritonitis.

The diaphragm was on a level with the fourth rib on the right side and the fifth rib on the left side. There were loose old adhesions binding the upper lobes of both lungs to the chest-wall, and each pleural cavity contained about six ounces of clear serum. The cavities of the heart, especially the left auricle and ventricle, were dilated; the valves on the right side were competent; the aortic valve was competent. There were vegetations on the free border of the cusps of the mitral valve; these vegetations extended from the auricular surface of the posterior segment of the mitral upward on the posterior wall of the auricle a distance of two inches. The muscle-cells of the heart had undergone fatty degeneration very generally.

The lungs were congested and intensely oedematous.

The upper lobe of the right lung was in the condition of red hepatization. The liver contained considerable fat and pigment. The spleen was larger than normal, pigmented and congested. The stomach and the intestines, in places, were congested. The left kidney was slightly larger than normal, surface was smooth, markings not very distinct.

On microscopic examination the tubules of the cortex contained much fat, and there were hyaline and granular casts in the straight tubules. The right kidney was very small, about twice the size of a normal supra-renal capsule; it was composed almost entirely of fibrous tissue. The kidney structure was barely recognizable, and no interference with the vascular supply or the ureter had been noticed to account for the atrophy of the organ. The bladder, vagina, and uterus were normal.

Both ovaries were displaced downward and forward, and there were adhesions (old and loose) stretching from the left ovary to the rectum, and from the right ovary and Fallopian tube to the fundus and posterior wall of the uterus. The right Fallopian tube was converted into a sac, which contained two drochams of pus, in which were found columnar ciliated epithelium. The left Fallopian tube was in a similar condition, but very much less distended. The ovaries seemed to be a RATHER UNIQUE SPECIMEN OF URINE.

It was passed by a woman fifty-five years of age, who was under the care of Dr. M. O. Terry. The patient passes, for two, three, or four weeks, an enormous quantity of whitish shreds with her urine, and micturition is very painful. She has done this almost continuously since childhood. The urine looked flaky, and the sediment presented a peculiar glossy, shining appearance. Examined microscopically it was found to consist almost entirely of dried epithelial elements. Beside a small number of cholesterone crystals there were respectively large numbers of crystals of urate of soda in the form of sheaves described by Uitzman. All the features of the case pointed toward the diagnosis of dermoid cyst, very likely in communication with the pelvis of the kidney. Dr. Heitzman said to Dr. Terry that if the pain was severe and the patient's health was being impaired, it would be justifiable to cut down and look for a dermoid cyst. Not having heard from the case for a long time he wrote to Dr. Terry, and received a letter stating that the woman continued the same as she had been during the last forty or fifty years, and that this peculiar appearance of the urine is seen every two or three weeks. Dr. Heitzman showed the specimen to illustrate the epidermal masses such as are seen in dermoid cysts, and also the urate crystals of the sheave-like form described by Uitzman.

On motion, the specimen was referred to the Committee on Microscopy.

Dr. J. A. WYETH presented a specimen which demonstrated one of the many uses of

THE ELASTIC LIGATURE.

It consisted of a part of the remains of an enlarged thyroid gland, with the ligature attached, one-half of which he removed, and had already published an account of the operation. Dr. Wyeth applied several ordinary ligatures to bleeding points, but they were of no avail, and he finally surrounded a small mass of vascular tissue with the elastic ligature, and had no further trouble from hemorrhage. The ligature was allowed to remove itself, and when it fell no hemorrhage occurred. He thought there was no safety in applying an ordinary ligature to a vascular tumor.

ANGIOMA OF THE VOCAL BANDS.

Dr. L. ELSEMBERG presented a tumor he had removed from the larynx of a man twenty-eight years of age. It was situated upon the right vocal band, very near the an-
terior commissure, and was about the size of a large pea, dark in color, and to the probe was soft. It was diagnosed as angione of the vocal bands. Macro-
scopically the tumor looked very much like a sponge. Microscopically it was made up of blood-vessels chiefly. This variety of tumor of the larynx is very rare, there being only a very small number on record. All those tumors which have been described have had their seat near the anterior commissure, and usually on the right vocal band.

The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE

SECTION IN OBSTETRICS AND DISEASES OF WOMEN.

Stated Meeting, November 22, 1883.

ALEXANDER S. HUNTER, M.D., CHAIRMAN.

DR. W. M. CHAMBERLAIN read a paper entitled

NOTES ON MALPOSITION OF THE UTERUS.

The mechanical treatment of uterine displacement has been one of the most arbitrary and empirical departments of our art. Dating back to Hippocrates, it has obtained a varying degree of attention down to the present time. For brief periods new methods and instruments have been multiplied, and then experience of their insufficiency, and even of their mischievous tendency, would lead to temporary discontinuance and abandonment, to be followed by a renewal of interest in the subject and new series of experiments. There are many men of good repute who seldom or never employ pessaries, denounce them as barbarous in conception, irrationally, uncleanly, inefficient, and even very dangerous, and in any given case their strictures may be perfectly just. But most of us can recall in our own experience many cases in which they have proved to be the least of two evils, and some of us have series of cases in which they have proved means of greatest comfort and advantage.

Obviously in estimating and discussing malpositions, it is first necessary to understand normal positions. Should the word be used in the plural? Is there more than one normal position of the uterus? The range of normal motion, makes excursions around a normal centre of motion, and is probably seldom, during life, absolutely at rest in that position. There is one limit of physiological motion, another of mechanical mobility, and a third of morbid extension. The lateral mobility is slight, not more than one inch for the healthy organ. On the other hand, the uterus revolves with great freedom upon a transverse axis, the axis of retroversion and anteversion.

By normal position is meant that situation to which in the healthy subject it tends to return from its excursions, and in which it remains in the equation of all the forces. A great deal of careful study has been given to the determination of this position in the last decade. It is with respect to the position of the fundus that there has been the most discrepancy of opinion. All agree that the infantile uterus is strongly anteverted and anteflected, and that it remains so through childhood. Opinion hitherto has been that with the advance of puberty the organ gradually erects itself, but the continental observers think that this erection amounts to much less than has hitherto been supposed. Fritsch and Schultz have even teach that unless the organ be pushed back by a full bladder, or by the descent of intestines into the cul-de-
sac anterior to the bladder, the plane of the anterior wall departs from that of the vagina by only a small angle, say ten or fifteen degrees.

This view of late has received much confirmation from the extraordinary clinical observations of Vedeler, of Christiana, Norway, based upon the examination of 5,012 adult women, 466 virgins, 740 multipare, 322 women in the first month of pregnancy, and 1,465 non-parous.

The forces which disturb the position of the womb act from the abdomen above it—the pressure of the intestines actuated by the impulse of the diaphragm in respiration, and by whatever may occasion contraction of the abdominal muscles. The effect of these forces will depend upon the balance between them and the power of resistance in the womb and its supports.

When the womb is so placed that the impulse from above is received upon the comparatively thin superior border of the fundus, the pressure wave shall not only disturb it least, but dividing and passing before and behind it will impinge upon the pelvic floor, and by repercussion will steady and support the organ. In this position the longitudinal fibres will also best maintain its position. It is therefore rational to suppose that the uterus, having free mobility in its transverse axis, is continually being itself to this position of elevation, in which it may feel the disturbing force least and be best able to resist it, the direction of the wave varying with the tension of the abdominal wall and the attitude of the body.

If, then, a woman complains of pelvic pain or other symptoms, and at the same time presents a marked ante-
flexion, whether or not forcible anteversion, the anteflexion is to be treated; or if it be removed, that there will for that reason be a cure of the case. It remains, then, to explain these cases in which anteflexions have been recognized and mechanical treatment pursued until the anteflexion was overcome, the patients recovering health with the cure of the anteflexion. The explanation must be sought in the subject itself to this position of elevation, not only for the cure of the anteflexion, did remove other conditions upon which rather than upon the anteflexion the symptoms in reality depended. In the same way retroversions may exist without producing symptoms.

Assuming that these views are correct, the practical inferences which follow them are of much importance.

First.—It is evident that the correct position in regard to the axis of the uterus is not the one for which the pessary was designed.

Second.—The discomforts and the negative results which notoriously have attended the use of anteflexion pessaries thus appear avoidable.

Dr. Chamberlain then proceeded at some length the character and relations of the tissues upon which the force of pessaries is exerted.

The mode by which flexions and displacements occur seems to be somewhat as follows: From impaired support beneath, due to relaxation of the underlying tissues, the uterus first descends, until it encounters a more or less fixed resistance. The weight of the organ, and the intra-abdominal pressure continuing, and descent being for the time restrained, the womb bends at the junction of the body and the cervix. Whether it shall be a forward or backward displacement depends upon causes which it is difficult absolutely to determine. Version and flexion occur together. Whether flexion shall predominate over version, or the reverse, or whether both shall be less than descent, will depend on the comparative softness of the tissues around the os internum as contrasted with the rigidity of the pelvic floor. In the greater number of cases the intra-vaginal portion moves in the opposite direction from the fundus, but in all, the organ, as a whole, descends more or less. It is probable that subjective symptoms do not arise until the process of congestion has somewhat advanced. It is the congestion, the prolapse, and the ligamental tension, rather than the version or the flexion, which are painful.

By extending the vagina in both directions, longitudinally and laterally, pessaries restore, in part, the loss of tension of the soft parts; by their own rigid outline they distribute unavoidable pressure over larger areas and antagonize partial and limited contractions, much as plaster to the wall of the thorax unites the action of the
separate intercostal muscles, and perhaps as much in any other way, they cut off the friction which attends the continued motion of the soft parts sliding upon each other. How else are we to explain that a simple oval ring is constructed and the condition which permits of the use of pessaries. The best material is hard rubber. The use of soft rubber is to be deprecated, because it almost invariably produces excoriations. A few years ago he recommended celluloid, used as a covering for soft copper wire, but since then he had found that they become brittle by keeping. This objection, however, does not apply to them when in actual use. The current statement that hard rubber instruments can be bent to any shape by heating them in the flame of a spirit lamp is not practically true. It is impossible to warm to equal softness all parts of the instrument in this manner, and a much better way is to lay the instrument upon a piece of pasteboard and place it in a moderately hot kitchen oven. This will make it quite pliable.

It is a common error to choose too large an instrument. A complicated outline is generally to be avoided. Many instruments are made with their surfaces too small. Pessaries should not be used with the idea of thereby gradually repositing a displaced organ; they are to prevent the return of the uterus, it having been proved to so effectively. They are used in the acute stage of local inflammations. On the other hand, the presence of great and painful engorgement does not preclude the guarded use of a pessary. The condition often depends on the displacement, and the best way to get rid of it is to reposist the womb and keep it in place. The use of pessaries should be the last resort in young unmarried women, and in hysteria from psychic causes. A pessary should almost always be promptly removed if it causes pain or fails to confer relief, and every woman wearing a pessary should present herself for examination at frequent intervals.

Dr. Chamberlain then exhibited about twenty varieties of pessaries in more or less common use, and indicated the reasons for this. He showed that such instruments that violated the conditions of extension rest and support previously stated. He gave preference to the "Albert Smith," the arms of which should be not less than one centimetre or four-tenths of an inch in diameter and the ends but slightly curved, and to the Fowler cup, and thought they could be made to meet almost all the indications.

Dr. P. P. Foster did not have the pleasure of listening to the first part of Dr. Chamberlain's paper, but in the latter part he had been much interested. He did not believe that any pessary acts as a lever. What a pessary does is this: A retroversion pessary acts almost always, if not always, by carrying the loose posterior wall of the vagina backward, usually somewhat upward, dragging the cervix in a retroversion and retroflexion, and not giving it up to take an opposite direction. In order for the retroversion pessary to act by making direct pressure upward and forward on the body of the organ, as stated by most authors, the pessary must be exceedingly long, much longer than he had ever seen in use; and, besides, it must have an exaggerated curve, even more so than that illustrated by Dr. Noeggerath's instrument, which had been shown.

In the next place, if the limbs of the pessary were far enough apart to allow the cervix to hang free between them, it would be so wide that it would spread the uterosacral ligaments apart, and, whatever support it might give temporarily, the last state of that woman would be worse than the first. For as soon as its use is discontinued the ligaments will be found still more relaxed than at the beginning of the treatment. As they constitute a sort of natural obstacle to retroversion of the uterus, there would be no natural tissue left to counteract such displacement. How, then, can stretching of the uterosacral ligaments permit of the use of another instrument be employed which is small enough to go up between the ligaments and not push them apart? Dr. Chamberlain has brought out this objection in all pessaries, and had said that their bearings should be small and make pressure upon a limited area. A pessary small enough in its upper arch to pass between the uterosacral ligaments without stretching them would not, probably, be well borne if worn continually. Now, that objection and several others may be gotten over by using pessaries which are not worn continually. Dr. Foster never employed a pessary which the patient could not introduce and remove herself, and she is always instructed to remove it at night. By this intermittent action it is perfectly possible to use a pessary with small bows which pass readily between the uterosacral ligaments if necessary, but it is not often necessary.

The form of instrument which he used gave him opportunity to add to what Dr. Chamberlain had said with regard to celluloid and copper wire. He had used this material constantly ever since Dr. Chamberlain introduced it, and not only does it hold its shape greatly, but it deteriorate by keeping. He had one patient who had worn this kind of pessary constantly ever since Dr. Chamberlain introduced the material, and it was yet in good condition. The instrument which he always used for retroversion is made for each patient. He had the instrument maker simply make a rod of copper wire covered with celluloid and put in place, the rods which are from twelve to eighteen inches in length, he fashions a pessary for each patient, bending it in the middle for the pessary bow, then having it run out to the vaginal outlet almost straight, and then it curves down abruptly to form the part which impinges against the anterior surface of the perineum, one leg bending backward and the other curving forward. In this way the lever action is avoided.

In regard to anteversion, he thought, with Dr. Chamberlain, that neither anteversion nor anteversion is very seldom relieved by treatment. He did not believe that anteflexion could be at all influenced by mechanical treatment except by stools, which he never used. He thought that it is not that these displacements are peculiarly. The only cases proper for treatment are those in which physiological anteversion or anteflexion of pregnancy gives rise to a good deal of suffering, and under such circumstances the pessary may be used as a temporary measure until the uterus is sufficiently large to rise out of the pelvis.

In some instances the pessary is of use where the displacement is not very prominent before it is applied, but it is not for the purpose of overcoming the displacement that the pessary is employed. Sometimes the pessary is beneficial by actually increasing the displacement. A great majority of displacements are due to contraction of inflammatory exudations. Now, if you have a band, say an organized mass extending from the body of the uterus back to the promontory of the sacrum, you can readily imagine that there is a constant strain upon that, which gives rise to pain on any movement of the body, particularly any sudden movement brought to bear upon this sensitive pathological structure. Under such circumstances a pessary can be so adjusted as to prevent any such sudden movement and even exaggerate the existing displacement.

Dr. Paul F. Mundt said he felt as much interested in this subject as any in gynecology. With regard to the normal position of the uterus, it seemed to him very curious that so many authors disagreed on this point. The normal position is a variable one, and it is not fair to say that it is either anteversion or anteflexion, for it is simply one of degree according as to whether the
bladder is full or empty, the rectum full or empty, the patient standing or lying, expiring or inspiring, quiet or in motion. The position described by Shultze and Fritsch as normal he had never found. The position which he had regarded as normal was that in which the axis of the vagina and that of the uterus met each other at a slightly acute angle, and from this it is movable one degree forward and more backward. In other words, the position which Dr. Chamberlain had described was the one which he would accept, as it would give sufficient mobility for a remove one degree anteriorly and two degrees or more of normal mobility posteriorly. Dr. Mundé was unable to understand how Fritsch and Shultze had found the uterus lying flat upon the vaginal wall. Should he find a uterus in this condition he would call it an anteflexed pathologic uterus. The position of the uterus varies according to whether the woman is standing or lying. In the standing position there is more anteversion than anteflexion, and the uterus is a little lower in the pelvis than when lying, and the fundus is slightly turned toward the abdomen.

Speaking of the relative frequency of the different malpositions of the uterus, he had found that anteflexion, which he called a malformation of the uterus, was the most frequent displacement in nulliparas and the unmarried. The next most frequent form is anteversion with descensus, occurring in married women, and the next menstruation in menstruating or without retroflexion in women who have had children. He was thoroughly of the opinion, as had already been said, that the uterus first settles in the pelvis because the ligamentous support is relaxed, then the fundus gets below the promontory of the sacrum, then begins to be retroverted, and afterward retroflexed more or less. Occurs quite explosively.

The significance of these various displacements is a point of a good deal of interest because it bears upon the question of mechanical treatment. Anteflexion and anteversion produce no symptoms. The congestion accompanying them, or the spasmodic contraction, may produce dysmenorrhea, but the anteflexion itself does not do so. He has observed that the anteflexed fundus pressing upon the bladder ever produced any particular symptoms.

Anteversion will produce symptoms only in cases where the uterus is at the same time displaced downward to the extent of one degree or more. Symptoms are produced only when there is descent of the organ in both forms of anterior displacement.

With regard to retroversion, symptoms are present in a large proportion of cases, but not in every one by any means. A retroflexion produces more symptoms than does retroversion because there is more congestion of the uterus, and also it is more apt to be accompanied by prolapus of the ovaries.

There is another displacement which is not mentioned very much but which produces symptoms, the chief of which is sterility. It is a combination of retroversion and retroflexion. He had always taken it to be a congenital condition, the ligaments never having developed in proper relation.

With reference to the causation of these different displacements, he thought that Dr. Foster had touched the key-note with regard to one cause, namely, the contraction of one or other of the ligaments, and chiefly the utero-sacral and lateral ligaments in the production of lateral or retro-displacements. He thought that few anteversions depend upon contraction of the lower folds of the utero-sacral ligaments just above Douglas' pouch. These cases, however, are exceedingly rare. He had seen retroflexion and retroversion in young unmarried women, but they were of very rare occurrence.

With regard to pessaries, he should at once take issue with Dr. Foster concerning the lever principle. He would agree with him perfectly that the effect of the retroversion was to push the posterior vaginal wall backward and therefore antevert the uterus, but he could not help feeling that when the Albert Smith or Hodge pessary was used, lying loose in the vagina with its anterior bow loose, pressed down upon in the erect position, pressed by the full or the empty bladder, or the intestine full or empty, that this instrument must necessarily tilt up at the other extremity, and in that way he thought it illustrated the action of the lever principle.

He used but few anteversion pessaries, but that which he favored most was the open cup of Thomas. For anteflexions he used the closed cup, as it prevents the uterus from flopping together. He had seen good results from gradually heightening the cup as the displacement was gradually being overcome.

For at least ninety-five per cent of retroversions he preferred the Albert Smith pessary. If there is flexion he prefers a pessary with a thick bulb—a simple Albert Smith pessary with a thick bulb behind. He might change the curve of these pessaries very often, but they were substantially the same instrument. Dr. Chamberlain and Dr. Foster have shown that pessaries did not work well. To this Dr. Mundé thought there might be some exceptions, but as a rule probably they are not well worn. Of late he had found the Cutter pessary to serve him a very useful purpose in the treatment of retroflexion. He admitted there was a tendency to push the cervix forward, but if the curve at the lower portion of the instrument is at a right angle, this tendency will be mostly overcome. The Fowler pessary he had used, but he did not like it.

With regard to the substance from which pessaries are made, he had tried celluloid and had had the same experience related by Dr. Chamberlain, namely, that the instruments cracked and became unfit for use, consequently the metal pessary is used regularly.

The Chairman said with reference to the pessary acting as a lever, that it must necessarily do so if there was a fulcrum. If the broad ligaments are tense, the uterus high up, and the vagina keeps positively its contracted condition, then he could see how the Albert Smith pessary acts upon the lever principle. On the other hand, when the anteflexed fundus pressing upon the bladder ever produced any particular symptoms.

Dr. Chamberlain, in closing the discussion, said he had no criticisms to offer to Dr. Foster's remarks, except possibly upon the lever action of the instrument. He felt confident that there is such a lever action, perhaps not to a great extent, nor exerted by all instruments.

With regard to the points made by Dr. Mundé concerning the normal position of the uterus, they were substantially what he had stated in his paper, and did not conflict with any position which he attempted to take. He thought there was a good deal in the idea that the position of the uterus in individual subjects was largely influenced by the contour of the abdominal wall, the impulse obtained from the descent of the diaphragm, together with the varying degree of the tension and weight of the intestines.

The Section then adjourned.

TESTING FOR ALBUMINURIA.—D. J. C. Neal, of Archer, Fla., writes: "Is it on record as diagnostic of albuminuria, that a portion of urine, if shaken in a test-tube or bottle, develops a foam or "beady" stratum on top—quite permanent if the albumen be in any quantity? This occurs early in the case, long before the dyspnea pallor or anasarca, and is perhaps the first indication of the disease." We believe that the same appearance results from the presence of pus and mucus.
Correspondence.

THE CHANCES OF THE YOUNG PRACTITIONER AND THE CLINIC SYSTEM.

To the Editor of The Medical Record.

Sir: The letters recently published in The Record upon the abuses of medical charities, and especially the editorial comment on those letters, have brought to the front a subject of the most immediate interest to practitioners. We are clinic-ridden and dispensary-ridden; our means of livelihood are taken from us, and the public is pauperized to an extent which is almost incredible. So great is the contest for "material" that all manner of inducements are offered to get people to receive medical charity. "Free dispensary," "free hospital," "an experienced physician sent free of charge to confinement," such are some of the advertisements which, in various languages, are displayed in the streets. People of the middle classes have become so accustomed to receive the best medical service for nothing that it is no wonder they prefer the clinic to the physician's office. And it is a scandal to see some of the patients who frequent these clinics. I can vouch for the fact that in some of them, at all events, it is by no means uncommon to see "charity" patients kid-gloved and dressed in silk. And they must all be treated, and most carefully and tenderly treated, too, for the professor (who has a lucrative private practice) wants all the material he can get.

There are at least 111 institutions in New York City in which free medical attendance is offered practically to all who choose to apply for it. It is safe to say that the existence of fully one-half of them is an infringement upon the rights of a very large proportion of medical practitioners. Fully one-fourth of the paupers treated at these institutions could pay a fee and ought to pay one. Surely the prices for which some of us have to work are within the reach of the slenderest purse.

But a small minority of the profession is directly interested in keeping up and extending these institutions. Probably not over ten per cent. of the city practitioners are connected with them. I do not include the younger men, the assistants, etc., in my estimate—for they are compelled, merely as a matter of self-protection, to take part in them—and they recognize and feel, perhaps more than others, the injury that the system works. It is but another form of the old problem, the infection of the useful and fruitful few is opposed to those of the weak many. The problem has been solved in other spheres by the elaboration of one idea—co-operation; and that, I take it, is the sole thing that will help us here. Individual action is of small avail, but united protest may do much.

This, it seems to me, is our only hope. If there is any channel of selflessness to permit of union for so desirable an object, much may be done to check an evil that grows in extent year by year. If there is not, why then, each man for himself, and "Veni, vidi, vici!"

It is hardly for me to say just what lines such a movement should follow; but I would suggest the following points:

First.—Medical services should no more be gratuitous than are legal and clerical ones. A poor client can have a lawyer "assigned" to him; but he must apply publicly to the courts for it, and he must sue in a special manner, "in forma pauperis;" such services are very rare, and any claim for them is well investigated before it is allowed. Clergymen go as preachers and missionaries among the poor, but they get their pay, whether it comes from mission boards or from subscription lists. Hospital interns, dispensary physicians should be salaried officers, and the benevolent individuals who pose before the public as the main supporters of such institutions, could do so with a better grace when two-thirds of the charity does not come directly from the pockets of a few medical men.

Second.—Dispensaries, hospitals, free clinics are superabundant, pauperizing the people. Their extension is objectionable, and the existence of many of them is unjustifiable. The six large dispensaries have the whole city districted and covered by their physicians; every branch of medicine receives attention from them, and they might readily be made to supply the material necessary for clinical teaching.

Third.—Some system should be elaborated by which medical charity would be restricted to paupers. I distinctly claim that one-half, if not more, of all the free patients in this city are not paupers in any sense of the word, they would resent such an assertion, and they are no more entitled to free medical services than they are to free clothes, or free bread and butter.

Such, it seems to me, are the main points that demand attention. I trust to the expression of other views for extension, or, if need be, for correction.

G.

HOT-WATER INJECTIONS PER RECTUM TO ARREST UTERINE HEMORRHAGE, TO PREVENT MISCARRIAGE, AND TO ALLAY AFTER-PAIN.

To the Editor of The Medical Record.

Sir: Having for the last four years used hot water, i.e., water at a temperature ranging from 110° to 112°, with perfect success in such cases as are mentioned above, I have determined from time to time to give my experience to the profession, but not being fond of writing, have delayed, and was only prompted to do so this night on reading an article in The Medical Record of December 15, 1883, on "Hot Water Douche in the Treatment of a Case of Post-partum Hemorrhage." Having never tried the hot vaginal douche in such cases, for the reason that I consider it not the most rational way of applying the hot water, I will give the treatment which I have practised, and which, so far as I am aware, is original. The first case so treated I reported to the Augusta Medical Society about four years ago, and as none of the members at that time had ever heard of the treatment before, I hope I may be excused for thinking I had made a discovery which might be of benefit to mankind, or at least womankind. Writing from memory alone, my first case, Mrs. T., I was called to her at midnight, found her in a pool of blood, very cold, and was for the youngest child four years of age. I was informed that she had missed her menses once or twice preceding this hemorrhage, but thought nothing of it, as she had done so before, and then came all right. I made a digital examination, found os dilated enough to admit end of finger; gave fluid extract of ergot in 3 doses, then ergot fluid extract, aqua, & & , with hypodermic injections of cold foot of bed, etc. Failing with all, after working for four hours, the idea occurred to me to give a hot enema in preference of trying the vaginal douche, for at best the hot vaginal douche is a very tiresome proceeding, if properly administered, both to the patient and the operator, to say nothing of wetting up everything, as not one patient in forty has a rubber cloth and other conveniences. Again, the injection of warm water, from a pint to a quart, into the rectum, is easily done and is over with, and you then have the water where you want it and not where you don't want it, viz., in the bed.

But my main object in injecting warm water per rectum is to put the water in as near contact to the womb and tube as is possible for the patient to hold it, and if the first feels uncomfortable, allow it to be passed off, of course, but replace it with another, which will be better retained. In this case the first was retained and acted like a charm. All hemorrhage stopped for the time; it returned once during the next
day, but was again checked with another hot injection. The second day the patient passed a tumor about the size of a large hen's egg, which proved, upon examination, to be a blighted ovum. And here I would remark that a great many of our profession seem to overlook the fact that a large number of cases of uterine hemorrhage are caused by contractions of the womb, as was the case in this instance, and those who will persist in treating all cases with ergot, packing, and punching, may naturally expect to do more harm than good in many instances.

Case II.—Mrs. S——, young mother, in full health, first child six months old, at the breast. Informs me she is all right except that she floods every two weeks. Has been treated by her physician with ergot, etc., to no effect. The trouble dates from birth of child.

Treatment.—Advised her to take an enema of hot water every morning. Later she informed me that the hot water brought her all right. I judge it did, as she conceived in three or four months, and at term was delivered of a healthy child.

Case III.—Mrs. D—— called me to attend her in confinement of this her third child. Found her in pains and the os dilated, size silver twenty-five cent piece. Informed her that I had treated her well, and to have an easy time would advise her to take a large warm enema to empty the bowels. On returning to the room she informed me that, to be doubly sure, she had taken two enemas of real hot water. The consequence was she had not another pain for ten days, at the expiration of which time I delivered her of a fine, large girl, weighing ten pounds, but I did not suggest to her any more hot water.

Case IV.—Mrs. M. B——. Found her flooding, not excessively. Showed me a clot of blood that had been passed, and informed me that she had passed others. Not believing in the mischievous or not, had her given the hot water per rectum. Bleeding ceased, and in about six months I delivered her of a well-natured boy. I should have stated that she knew she was incontinent when I was called in to attend the hemorrhage, having missed her courses and suffered with morning nausea.

Well, I could recount other cases, but imagine I hear you say "Don't, please don't." However, you must in all fairness allow me to give my theory of the action of hot water so used. It is not that the water so used arrests hemorrhage by producing contractions of the womb, for I believe just the contrary—i.e., I believe that warm water of temperature 110° to 112°, brought in close contact with the womb, either per rectum or by injections into the bladder, will arrest contractions of the womb, and at the same time arrest hemorrhages by driving away the blood from the surrounding parts, equalizing the circulation, and reducing any existing congestions.

Respectfully, A. E. Dugas, M.D.

345 Broad Street, Augusta, Ga.

The Proposed Monument to Dr. J. Marion Sims.

To the Editor of The Medical Record.

Sir: A writer in a recent number of your journal suggests that a monument should be erected in memory of Dr. J. Marion Sims, and that the proper place for it is the Central Park, New York. While the memory of Dr. Sims does not require any bronze or marble for its perpetuation—for his name is immortal—it would, it seems to me, be highly proper that such a mark of respect should be paid to the character of a man who accomplished so much for his profession, and who was such an honor to the country. Monumental works are built for the benefit of the dead but as a stimulus to the living, to excite their ambition, and to arouse them to the performance of noble deeds, by imitating the example of those who, while upon earth, spent their lives in doing good to their fellow-beings. As Dr. Sims was the founder of the New York Woman's Hospital, it is highly proper that the medical profession of New York should take the initiative in this matter; and while the members of the profession in all parts of the country should, may would, regard it as a privilege to contribute to so praiseworthy an object, an essential appeal should be made to the women in all parts of the world who have been the recipients, either directly or indirectly, of the benefits of Dr. Sims's genius and skill. I would respectfully suggest that a committee, consisting partly of gentlemen and partly of ladies, be at once formed to take charge of the matter and to give it definite shape. As soon as this object is effected it will afford me pleasure to send you my check for $100.

I am very respectfully, your friend,

S. D. Gross.

Philadelphia, December 24, 1883.

New Instruments.

A NEW TISSUE FORCEPS.

By B. Cowper Shenstone, M.D.

Brooklyn, N. Y.

The accompanying woodcut illustrates a new style of tissue forceps made for me by Mr. Fred. Haslum, of this city. I, with others, have felt the necessity, in operating upon the cervix, of an instrument to steady the tissues through which the needle must pass more perfectly than the counter-pressure hooks will do. This instrument combines the counter-pressure hook and tissue forceps, both blades of which are perforated for the passage of the needle, while the tissues are held steadily in the grasp of the forceps with as much or little firmness as may be desirable. It has become almost indispensable in my hands, I therefore deem it worthy of presentation to the profession, and hope it may in a small degree simplify operations of that class.

The Equable Scrotal Compressor.

By G. Miliano, M.D.

New York.

Believing that support and pressure are the main factors upon which we are to rely for controlling and removing the effects of increased vascularity in scrotal diseases, I devised, many years ago, an apparatus having such ends in view. Its favorable reception by my professional brethren impresses me with the fact that the principle upon which its construction is founded is sound. Since its first introduction to the medical public some improvements in construction have been made which I believe will increase its usefulness and extend its range of adaptability.

It is perhaps best to describe the perfected apparatus as it now is, and its mode of application, in order to come directly to the purpose of the present communication. The cut herewith represented gives a better idea of its construction than can be done by mere words. It is, in brief, a netted silk pouch for the scrotal organs, which can be compressed in any portion at will by shoving the encircling tapes in its meshes, and suspending the whole by means of bands to the waist. The penis is received in the circular opening in front, which opening can be enlarged in any direction for forced displacement of the organ without weakening the fabric. The posterior and upper edge of the pouch is provided with
similarly shirr and tie the lowest set of lacing, which closes and shortens the bandage below the testicle (marked C). This produces counter-action and pressure against the upper set of lacing, care being taken to exclude any fold of the scrotum.

The next lacing above the lowest set (marked B), which encircle the middle of the scrotal organs, should be shirred only snugly enough to be comfortable. In a few hours, according to the nature of the disease (as in the reduction of varicocele) the compression acts upon the absorbents, and the enlargement of the scrotal organs begins to abate. As this reduction of the scrotal contents progresses, the sets of lacings (marked A and B) are to be tightened in order to maintain equal compression.

It is well known that in cases of epididymitis the disease must be arrested at once, or the epididymis will become indurated and closed, and the excretory duct of the testicle loses its function; in other large swellings, where rapid reduction is necessary to effect a cure, a bandage of large size containing more lacings becomes indispensable. In such cases the same rules for applying and shortening the bandage as above stated will be followed. They are manufactured of silk, linen, and cotton fabrics, mixed, and for ordinary purposes are made in three sizes, No. 1 being the smallest, No. 2 medium, and No. 3 the largest.

The Cartwright Lectures for 1884 will be delivered by Prof. Burt G. Wilder, of Cornell University, at the hall of the Young Men’s Christian Association, corner of Twenty-third Street and Fourth Avenue, on the evenings of February 2d, 4th, and 6th. The general subject will be “Methods of Studying the Brain.”

The Value of Vaccination against Anthrax.—A commission consisting of Professors Maggi, G. Sormani, and E. Perrottetti, and Dr. Nosotti, was appointed to investigate the prophylactic value of vaccination with the cultivated anthrax fluid by the method of Pasteur. They experimented with calves, heifers, and lambs. Their conclusions are as follows (British Medical Journal): 1. Pasteur’s method of carbuncular vaccination is prophylactic of carbuncle in the bovine race. The six vaccinated animals received no harm from repeated injection of carbuncular blood, while the four unvaccinated had high fever and great local swelling.
The heifers virgin to carbuncular injection, subjected to inoculation of blood and carbuncular virus, presented febrile reaction, but did not die; the immunity which the two first heifers of control, the malady caused by the injection of carbuncular blood having ceased, acquired in the prepared injected, the second experiment, would seem to show that the morbid process was really carbuncular in nature. 3. Vaccination with attenuated lymph (No. 1, Pasteur), although repeated, caused no general or local reaction. This allows us to suppose that its action is so slight as to justify the attempt, already successfully made by Perroncito, to omit the first vaccination, and thus gain valuable time. 4. After using the stronger lymph (No. 2, Pasteur), its action should be verified by observing the temperature for a few days. It is reasonable to suppose that the preventive effect is limited to those animals in which a general reaction is developed. If there be no reaction, therefore, the vaccination must be repeated. 5. Cool weather is best for the vaccination; in the heat of summer, the occurrence of septicemia is more to be feared. 6. The microscopic examination of the vaccine liquid prior to its use is necessary to prove the absence of bacteria of putrefaction, which, while they might destroy the prophylactic action of the vaccine for carbuncle, if injected, might easily give rise to disastrous consequences.

VOLUNTARY INHIBITION OF THE HEART'S ACTION.—Dr. C. A. Brooks, of Harrison, N. J., writes: "There is a man in my neighborhood who claims he can control the action of his heart by will-power, for he has tried the experiment several times, and once he was hardly able to detect his heart beat, and scared himself badly, fearing he would not be able to gain control of its action again, although he did not lose control of it. Do you know of a precedent to this? Is it not rare? He is about forty-five years of age, German, healthy and intelligent. He thinks his fee of $500 per annum would be good to good effect by exhibiting himself." Most physiological works relate the history of an Englishman, Cole Townsend, who could voluntarily check the action of his heart until pulse and heart action were almost imperceptible. He died in one of these attempts. Several other cases have been reported, and it is probable that voluntary inhibition of the heart's action is in rare cases possible.

CANCER AND OSTEO-SARCOMA AMONG CATTLE.—Rudolph Fuller, veterinary surgeon, of Grand Rapids, Mich., has a record of a recent case which he has tried the experiment several times, and once he was hardly able to detect his heart beat, and scared himself badly, fearing he would not be able to gain control of its action again, although he did not lose control of it. Do you know of a precedent to this? Is it not rare? He is about forty-five years of age, German, healthy and intelligent. He thinks his fee of $500 per annum would be good to good effect by exhibiting himself." Most physiological works relate the history of an Englishman, Cole Townsend, who could voluntarily check the action of his heart until pulse and heart action were almost imperceptible. He died in one of these attempts. Several other cases have been reported, and it is probable that voluntary inhibition of the heart's action is in rare cases possible.

CATTLE THE DISEASE.—The disease affected the same portion of bone on each side, though one side was much farther advanced than the other, pointing to a constitutional tendency as a cause in the disease. Though no microscopic examination was made of the diseased tissue, I think that the history and symptoms in the second case would warrant the conclusion that the disease was cancer. Horses are frequently affected with the same disease, which runs the same course and always terminates fatally. Though it is yet to be demonstrated that the flesh of cancerous animals is an unwholesome article of diet, the citizens of Grand Rapids are under great obligations to Dr. De Wolf, sanitary inspector of Chicago, for the information that some of these cattle were being shipped to this city. Inspectors should be appointed in every town and city to work in concert, in order to protect the public against ignorant and unprincipled rascals, who, to make a dollar, would be willing to send disease and death into every house.

PHOSPHORUS AND RED HAIR.—Dr. James S. Tracy, of Millbury, O., writes: "Once in a while in one's practice something happens so different from bad roads, poor farmers, and busy social occasions that it is worth recording as an event of every-day experiences to be forgotten. A case in point would seem to present a new contra-indication to the administration of phosphorus, at least it is new in this part of the country. A lady patient, whom nature had adorned with a color of hair which considerably out-auburned theauburn, needed, it was thought, phosphorus, and was accordingly prescribed for the same reason that many other invalids had been treated with that medicine. After taking them faithfully for a time, she noticed, either in the excreta or some place else, the phosphorescence, and rightly divining that the pills were causing the phenomenon, returned, and expressing a desire to discontinue the treatment, gave as a reason for so doing that she was afraid the medicine would get into her hair and ignite."

SOME NOTES UPON THE TREATMENT OF THE OPICUM HABIT.—Dr. A. P. Meyert, of this city, sends us the following: "The opium habit, in my experience, yields readily to the method of gradual reduction by prolonging the period between consecutive doses. The longer the delay the less of the drug is required. One patient, an habitue of ten years, taking ten drachms of Majendie's solution every day, in two doses, was thus reduced to fifteen minims daily in seven days, and the drug was discontinued within ten days. Another, who had for ten years been taking from one to two drachms of Gordon's in two doses, was brought down to nil in less than a fortnight. A neurotrophic patient had for twelve years been taking morphia subcutaneously, latterly seven to nine times in twenty-four hours, aggregating sixteen to eighteen grains daily. It was practically discontinued in about three weeks, the patient remaining under observation ten weeks altogether. Her physician informs me that she has steadily improved since her departure three months past, and considers herself cured both of the habit and the disease. A patient who had for thirteen years taken an ounce and a half of chlorodyne daily in one dose, discontinued the narcotic altogether in less than two weeks, and has found no special for the disposition. Treatment must be adapted to individual cases. The neuralgic pains and the distressing general hyperesthesia are usually soon relieved by quinine, two to five grains, and extract of cannabis indica, one grain, repeated in three or four hours if necessary. Warm baths are also very effective. Galvanism, the continuous, uninterrupted current, given in the morning, is also useful. Nausea generally yields quickly to small, frequently repeated doses of peptonized beef, acidulated. Insomnia ceases to be troublesome when the neuralgia and nausea are relieved. I am satisfied that the easiest and best general method of treatment for opium habituation—one which may be adapted to all cases—is gradually to increase the interval of narcotic administration, simultaneously diminishing the daily dose.
APOLECTIC SEIZURES. 
THEIR DIAGNOSIS AND TREATMENT.

BY HENRY M. LYMAN, A.M., M.D.,
PROFESSOR OF PHYSIOLOGY AND OF DISEASES OF THE NERVOUS SYSTEM, BUSH MEDICAL COLLEGE, CHICAGO, ILL.

DUJARDIN-BEAUMETZ ("Leçons de Clinique Thérapeutique," vol. iii., p. 254), improving upon the work of Schützenberger (Dict. Encycl. Sci. Med., Art. Apoplexie), has defined apoplexy as a "more or less sudden, complete, and persistent suspension of the cerebral functions, produced by an internally originated lesion of the circulatory apparatus acting directly upon the brain."

This excludes the effects of simple commotion or concussion of the brain on the one hand, and the consequences of asphyxia, syncope, and toxic forms of coma on the other. The perversion or loss of cerebral function is declared in the sensory sphere by a more or less complete arrest of sensation, perception, conception, and the reasoning faculties; while in the department of motility the change in cerebral function is revealed by the occurrence of muscular paralysis. This may occasion loss of power over only a few muscular groups, or it may involve the whole or the majority of the muscles of the body. The movements of circulation, respiration, and secretion— all movements, in a word, which are independent of cerebral action— persist so long as life itself is not overwhelmed.

The onset of apoplexy is usually quite sudden. I once saw a coachman, a middle-aged man, whose horses became ungovernable, and who, in their movements; suddenly he fell headlong from his box, and was picked up in a state of complete coma, with resolution of all the limbs. He died in a few hours, and the autopsy revealed an extensive rupture of the substance of the right hemisphere of the brain, with hemorrhage into both lateral ventricles. The arteries of the brain were empty. His pulse was feeble; and it is probable that the muscular exertion due to the effort to stop his horses, caused a sudden and extensive rupture of those blood-vessels without any special premonitory symptoms of apoplexy. Sometimes, however, there are such forewarning symptoms. A gentleman, about fifty-eight years of age, who had previously sustained an apoplectic stroke, called at my office one day, complaining of dull pain in his head, with bright flashes of light before his eyes, humming in the ears, a sense of weight in the limbs, and a vague anticipation of evil oppressing his spirits. I advised him to go home as speedily as possible, and to employ such derivative measures as would tend to relieve the evident determination of blood to the brain. He accordingly went home, retired to his room, and laid himself in his clothes upon the bed. In less than half an hour he became suddenly unconscious, and died in a few minutes.

In certain cases, though the onset is quite sudden, it is not instantaneous, and the abolition of cerebral function is comparatively gradual and progressive. A gentleman, about fifty-five years of age, while writing at his office desk one day, had occasion to cross the room for something. He laid down his pen, arose from his chair, took two steps, tottered, turned around, supporting himself with one hand upon a table, and sank back into his chair. He asked for his son, who was occupied in an adjacent room, and when the young man came in he said, "It is all up with me." On examination his side was found to be paralyzed. He quietly gave directions for the completion of the work upon which he was engaged, and was then removed to his house, where, in the course of a few hours, he became gradually insensible, and died the next day.

Sometimes, however, the attack, though alarming, does not thus progress to a complete paralysis or to a fatal determination. An elderly clergyman told me that one day, while engaged in the vigorous delivery of a sermon, he heard a noise as if a pistol had been fired in his head, accompanied by a sharp pain behind the right ear. Presently it seemed as if his left side were "going to sleep," and he found himself partially paralyzed upon the left side. He did not become unconscious, and was always able to walk with a cane; but it was more than a year before the paralytic symptoms disappeared.

The muscular paralysis which follows an apoplectic seizure is usually hemiplegic; but it is often limited to a simple limb, constituting monoplegia. I once treated an old negro, whose vivacity was unimpaired, and whose limited intellectual faculties did not seem to have been enfeebled. She woke up, one morning, feeling as well as usual, but unable to move her left arm. She never recovered the use of this arm, while the patient maintained his faculty of speech which is thus stricken by the cerebral lesion, the patient remaining permanently dumb, though he may recover, more or less completely, the use of his other faculties. These mutilations of the function of expression form a class of phenomena which require consideration by themselves.

It is occasionally difficult to decide whether the condition of the patient is due to apoplexy or to some form of poisoning. I once saw a middle-aged man who had been picked up on the prairie outside of the city, and was brought to the hospital in a state of complete insensibility and resolution. He had vomited, and had also evacuated his bowels into his clothes. His bladder was empty. His pulse was feeble; and it is probable that the muscles of the eyes were contracted; respiration was slow and stertorous; the pulse was feeble and of moderate speed; the skin was bedewed with perspiration. Was it a case of alcoholic poisoning? There was no smell of liquor about him. Was it opium poisoning? The pulse and respiration were too rapid for that. Was it uremic coma? Urine could not be obtained for examination, because the bladder was empty. Was it apoplexy? Both sides were alike flaccid and motionless. The temperature was rising rapidly. Might it not be a case of puerperal meningitis? Death occurred after a few hours, and the autopsy revealed a clot under the pons Varolii.

Successive seizures are not unfrequent. These occur usually at considerable intervals, permitting a degree of recovery which to the superficial observer may seem to be complete; but sometimes the intervals are short, as in the case of a boxum lady, forty years of age, who awoke one night in a state of agitation, with paralysis of her right side. She could not speak, but she could make a noise. The next day she seemed better—could sit up and read a book. For two days she thus improved; but while she was asleep, a second attack, which destroyed consciousness, sensibility, and all power of motion on the right side. When I first saw her, ten days after the attack, she was in this
condition, and presented no sign of perception excepting such as might be indicated by a tremulousness of the eyelids and the discharge of a tear as I counted her pulse.

The attack is usually caused by the result of internal disease; but a similar condition may be produced by external violence. A little boy, eighteen months old, was brought to my clinic with complete hemiplegia. He had fallen backward from a chair upon which he was standing, and was picked up insensible, with a great bump on the back of his head. He soon began to improve, and at the end of a year he could walk quite well, with only a slight drag of the foot, which would not be noticed by any one unawares of the incident which had occurred. For a similar case, but characterized by a more rapid recovery, see Le Progres Medical, September 8, 1883, p. 719.

But in certain cases recovery is far from complete. It sometimes happens that after several weeks of partial convalescence the paralyzed limbs become gradually deformed by contractures of their muscles. The fingers become forcibly flexed into the palm of the hand, the hand is flexed at the wrist upon the forearm; the forearm is pronated and flexed at the elbow, and the upper arm is drawn closely to the side of the body. Finally, a somewhat correspondent series of contractures manifests itself in the lower limb, crippling the patient for life. In this condition one of my patients, a gentleman over seventy years of age, was passing the last days of his life. His control of the bladder is diminishing, and his mental capacity is nearly gone, showing a most extensive process of degeneration subsequent to the original seizure. In another case which came under my notice, the hemiplegia being upon the right side, and accompanied by aphasia, the upper extremity became permanently immobile, the lower limb assumed sufficient tone to allow comfortable walking for nearly fifteen years before death. In this instance the patient could read, and could hear, but the power of articulate utterance and of writing were permanently destroyed. On one occasion, however, it became desirable to secure his signature to a legal document. The papers were laid before him, their contents were explained, and his signature was requested. He made the greatest effort to write, but without success, becoming greatly agitated in the attempt. Next morning he arose early, went down-stairs before any of the family were awake, and signed his name in as clear and legible a script as he had ever written. His case was complicated with post-hemiplegic epilepsy—the convulsions would occur at night, and as the result of the lower limb a more or less automatic attempt to carry out the directions laid down by Sir Thomas Watson. Three drops of croton-oil were laid upon the root of the old man's tongue, and his temples were liberally festooned with leeches till I could not but think of the poet's exclamation—

"Shake not thy gory locks at me!"

Presently the muscular agitation of the sick man was diminished; his cheeks ceased their puffing; finally the bowels were evacuated; and after a few hours my patient became conscious. He gradually recovered, and I frequently saw him afterward enjoying himself in his garden, apparently as well as before the alarming attack which had so suddenly befallen him. Unfortunately no post-mortem examination could be obtained. It would seem as if the accidental and temporary return of ability to sign his name had been an incident comparable with the so-called 'associated movements' which are sometimes observed after hemiplegia, when the patient raises the paralyzed arm during a movement of gaping or sneezing—a function of the purely automatic apparatus, independent of ordinary cerebral volition. But my space will not permit further discussion of such phenomena in this connection.

As a consequence of certain apoplectic seizures, followed by hemiplegia, various rhythmical movements of the paralyzed or paretic limbs are occasionally observed. A large and powerful man, between fifty and sixty years of age, started alone one winter day to go from a lumber-camp in Northern Wisconsin to another station, distant about fifteen miles. He rode one horse and led another. It presently began to snow; the track became obliterated, and the traveler found himself lost in a northern snow-storm, with a bitter wind rapidly lowering the temperature. He finally dismounted under a tree where he made the two horses lie down on each side of him, and drew a large tarpaulin over the whole group. He soon became unconscious, and when he awoke, three months afterward, he found himself in a hospital in St. Louis, with complete left hemiplegia. He then learned that on the third day of the storm his friends from the camp had found him insensible in the snow, with one horse dead by his side, and the other standing over him. They carried him, as soon as possible, to the nearest settlement, whence he had been finally transferred to St. Louis. When I saw him it was about three years after the attack. The patient was intelligent, and could walk with a halting gait, but there was partial contracture of the pronator and flexor muscles of the forearm, with rhythmical movements of the thumb and fingers, constituting a form of what has been described as post-hemiplegic chorea.

It is sometimes observed that during the evolution of paretic dementia, the patient may become quite suddenly unable to regulate his movements. I once attended a gentleman, aged about fifty-seven, who for a year after a sunstroke had manifested symptoms of progressive general paresis. He one day fell down upon the floor in a state of unconsciousness, with contracted pupils, slow and labored respiration, puffing with the cheeks, and conjugated deviation of the eyeballs. He was placed upon his bed, and, after several hours, gradually recovered consciousness and the power of motion, living several months longer before his death. It is highly probable that in this case there was a sudden and violent congestion of the brain without vascular rupture. Such was evidently the fact with an old man, seventy-one years of age, to whom I was called at an early period in his disease. He was a gentleman of large fortune. Four years of his life had been taken from him by his disease, and puffing respiration, swollen veins, and suffused eyes. One arm was motionless, but with the other hand he was continually fumbling at the genitals. Two excellent physicians had already pronounced the case hopeless, and had left the scene of action. On my arrival, not knowing of their previous visit and unfavorable opinion, I was allowed to take charge of the patient. Four or five months after I first saw him I removed him to a more rural station, and he lived for a year longer, during which time I was able to give him the most simple and necessary attention. On the fourth day Post-mortem section revealed endocarditis and articular rheumatism. Suddenly he became greatly prostrated, and his right side was paralytic. When I first examined him, a few hours after this incident, he was conscious, and could still speak with considerable ease. But the next day his right side was totally paralyzed, he could not speak, and he lay in a condition of complete apathy, dying on the fourth day. Post-mortem section revealed endocardial vegetations and complete occlusion of the left middle cerebral artery. My friend Professor Brower was kind enough, recently, to show me the brain of a patient who had suffered with right hemiplegia about two years before death. He had also been aphasic for about two months, and had then gradually recovered the power of speech. He finally died, and third branches of the Sylvian artery were occluded with embolic masses, and that portion of the cortex nourished by them had become atrophied to such a degree that it seemed at first sight like the cavity of an old abscess.

The vessels of the brain may become obstructed by
a local thrombosis. This usually occurs as a result of the cavernous dyscrasia, or of some infectious disease. I once saw a gentleman dying with cancer of the rectum, who for several days before death experienced successive paroxysms of intense pain in the head, followed by temporary coma. After death the lateral sinuses and large veins in the vicinity of the Sylvian fissure were seen filled with thrombotic clots. Another of my patients, a young girl, aged fourteen or fifteen, died on the fourth day of scarlet fever. She became comatose and convulsed before death. The entire cortex and meninges of the brain were in a state of the most brilliant hyperemia possible, and the superior longitudinal sinus was filled with clotted blood.

A thrombosis at an artery, yet very different, is the condition sometimes presented in the course of tubercular meningitis. Such a little patient, a female, aged two years and six months, I have just seen, stricken with right hemiplegia during the course of a slowly wasting illness, in which she is nursed by a consumptive mother. There can be only one result, and post-mortem section in similar cases has often revealed a tubercular nodule, or a thrombotic vein, pressing upon a cerebral peduncle, or upon some equally important portion of the motor apparatus of the brain.

Tumors, especially those of syphilitic or cancerous origin, are said to be the occasional cause of apoplectic attacks, by reason of hemorrhage from their vessels; but I have never seen a case of this kind.

Apoplectic may be caused by an abscess within the cerebrum. An old man was once placed under my care, who, in the course of a discussion with his wife, had received from that lady a blow upon the forehead with a tin dipper. The edge of the dish had inflicted a clean cut down to the bone, over the left eyebrow. There were no visible symptoms of a cerebral attack, and manifested no inclination to heal, and after several weeks the bone became necrosed. Still the patient continued to walk about, until suddenly one day he became comatose, with right hemiplegia, and death on the third day. Examination of the body discovered an abscess as large as a pigeon's egg in the centrum ovale, under the middle frontal convolution of the left hemisphere. This extensive accumulation of pus occupied a clean cut cavity in the white matter of the brain, and had occasioned no symptoms worthy of note until the final apoplectic seizure.

Pitres ("Lesions du centre ovale," Thèse de Paris, 1877, obs. 1) has recorded a case in which hemorrhage into the middle frontal convolution produced neither apoplexy nor hemiplegia.

The apoplectic attack may be very closely simulated by other diseases. It is worthy of note that after an epileptic fit a patient will sometimes appear to be hemiplegic as well as comatose. This counterfeit paralysis is supposed by Hughlings Jackson to be the consequence of a neuro-muscular concussion during the convolution. The history of the case, and the rapid emergence from a condition of insensibility will soon clear the diagnosis, except in the rare cases that are fatal during the period of coma.

Hysterical women occasionally pass into a sudden condition of seeming insensibility, which is sometimes accompanied by symptoms of hemiplegic paralysis. I was once called, in great haste, to a young girl of fifteen who had been subject to "fits." After a succession of these she had suddenly become apparently unconscious and completely paralyzed upon the left side. When I visited her the next day, the left side had recovered its moility, and the right side was now paralyzed, and also insensate, caused by a gastronomic retentive spasm. She was contracted in a semiflexed position. I confidently announced a speedy recovery for the patient, and, sure enough, on the fourth or fifth night, while the family were devoutly praying for the restoration of their daughter and sister, the girl, who had been nearly a week speechless, paralyzed, and comatose, bounced out of bed upon her knees in the middle of the circle, praying louder than any of the rest of the party. This was considered a miraculous answer to prayer.

Severe forms of malarial intoxication sometimes produce a condition of coma, which can only with care be distinguished from the ordinary apoplectic seizure. I well remember several cases which came under my notice during the civil war. Attention to the state of the temperature, and the evolution of the case were sufficient to establish the diagnosis; but it is easy to imagine that a brief observation of such a patient, without consideration of place, season, or history, might lead one into error.

Uremia poisoning also frequently causes a degree of coma and resolution comparable with the severest forms of apoplexy.

It would be an easy matter thus to multiply illustrative cases, but I forbear. It is evident that the apoplectic state may be induced by a considerable variety of physical conditions. Careful analysis of numerous examples shows that apoplexy may occur as a result of cerebral anemia, as a consequence of hemorrhage into or upon the substance of the brain, and, lastly, as a result of various alterations of the blood may be ranked a variety of cases which so closely resemble the apoplectic seizure that they are sometimes admitted into the same general class. If mere loss of consciousness were the essential feature of apoplexy, it would be necessary to classify under this term all cases of syncope, asphyxia, uræmia, epilepsy, and even hysteria; but there is an increasing tendency to exclude everything but the effects of direct lesions of the cerebral circulatorv apparatus. For all practical purposes, therefore, apoplexy may be considered as the result either of cerebral congestion, hemorrhage, embolism, or thrombosis.

The onset of an apoplectic attack is usually sudden. When preceded by premonitory symptoms they appear in the form of sensory disturbances, such as giddiness, humming in the ears, flashes of light before the eyes, feelings of numbness, and general failure of cerebral function. The attack may be almost instantaneous, plunging the patient at once into a condition of complete insensibility and unconsciousness, with general paralysis of the extremities, slow and stertorous respiration, contracted pupils, conjugated deviation of the eyes, turgid countenance, skin bedewed with perspiration, incontinent rectum and bladder. The pulse may be full, slow, and regular, and in fatal cases usually persists for a little time after the cessation of respiration. The body, however, is not the first, but, if life is prolonged for a few hours, it again rises, and may ascend beyond the normal figure. Death supervenes in such cases either immediately or after the expiration of a few hours. Post-mortem section discovers either extensive hemorrhage into the substance of the hemispheres, with rupture into the lateral ventricles, or smaller hemorhagic foci involving the structure of the pons Varolii or the medulla oblongata.

In many instances the seizure is less abrupt and overwhelming. Its onset is either more gradual or less profound. The patient feels compelled to lie down, and slowly passes into a condition of stupor, which may culminate in complete resolution and death, or which may, after a time, yield to convalescence and recovery. Long before either event the symptoms of hemiplegia become prominent, and a corresponding paralysis of sensation may also be demonstrated. When about to reach a fatal termination the symptoms deepen their intensity, and death occurs as in the fulminating seizure. When the reverse occurs, coma yields to stupor, and that to sleep, the patient remaining insensible and unconscious. The accompanying paralysis is more or less persistent—sometimes yielding in a few days or weeks, but generally continuing for months, or even during the remainder of life. Power of motion almost always returns first to the lower extremity, and may there finally become
more complete than in the upper extremities. In certain cases, three or four weeks after the attack, the flexor muscles of the paralyzed limbs begin to manifest symptoms of progressive contracture; the fingers bend into the palm, the hand is flexed upon the wrist, the forearm becomes pronated and drawn up near a right angle with the upper arm, which also is drawn closely to the side by the action of the muscles about the shoulder. The lower limb may, in somewhat a similar manner, be deformed by contracture, but this is a later and less severe event. These late contractures must not be confounded with the early rigidity of the muscles, which is often remarked as an immediate consequence of cerebral hemorrhage, for they are the expression of a peculiar degeneration of the descending pyramidal tracts consequent upon injury of the motor zone of the cerebral cortex, or the underlying fibers of the posterior radiata and internal capsule.

When summoned to the care of a case of apoplexy the first subject for consideration should be the nature and cause of the attack, for not every case of recumbent unconsciousness is apoplectic. Other diseases may occasion as complete loss of consciousness and power of motion. Prominent among these are syncope, asphyxia, epilepsy, paralytic apoplexy, and circumpartum conditions. The comatose stage of the eruptive fevers, certain forms of gout and rheumatism, malarial intoxication, and the poisonous effects of opium, belladonna, lead, etc.

Syncope may be excluded by attention to the condition of respiration, which is noisy, stertorous, and active in apoplexy, but almost imperceptible in syncope. The character of the latter also is reduced to the lowest ebb, while in apoplexy the pulse, though variable, is very evident, and there is frequently exhibited a strong tendency to venous and capillary stasis. To the syncopal category also belong those cases of collapse, followed by unconsciousness, which may supervene as a consequence of cerebral anemia. Apoplexy may be recognized by the peculiar respiratory character designated by dyspnea, with prolonged expiratory efforts culminating in labored inspiratory movements and death. The respiration of apoplexy is often retarded, but it is attended with symptoms caused by cranial nerve paralysis—puffing respiration, tracheal rattle, and, sometimes, the Cheyne-Stokes phenomenon.

Most apt to occur in the post-convulsive stage of the attack, appearances which closely resemble the features of apoplexy. Hemiplegia even may occur after epileptic convulsion, but its duration is brief. The history of the case and the rapid disappearance of coma are generally sufficient to enlighten the diagnosis. It is true, however, that certain cases of apoplexy are complicated by vascular spasm and appear epileptiform in the course of the life of certain apoplectic patients. In like manner the history and concomitant circumstances of puerperal eclampsia can scarcely fail to differentiate the case from apoplexy. As in the convulsive form of epilepsy, the post-convulsive condition may closely counterfeit the coma of apoplexy, but the evolution of the case is different. Uremic coma often presents the closest resemblance to apoplexy, with a high degree of muscular resolution. It may be differentiated by attention to the temperature, which diminishes as the coma of uremia deepens, but increases as apoplexy approaches a fatal termination. The comatose stage of the eruptive fevers and of cerebral rheumatism must be distinguished by the history of the cases, and by attention to other symptoms characteristic of such diseases.

Alcoholic intoxication may be recognized by the alcoholic odor of the breath. Certain cases of apoplexy associated with drunkenness cannot be thus speedily diagnosed. The progress of the case will, however, soon throw light upon the question of diagnosis. There is usually a more or less copious and copious, and temperature in ordinary intoxication than in apoplexy, and the presence of hemiplegia would be almost decisive in favor of apoplexy.

Lead-poisoning sometimes produces a condition of coma, with or without accompanying convulsions. Attention to the history of the patient, the presence of the blue line upon the gums, and, in very doubtful cases, the employment of electrical tests, will be decisive. At the same time, as Rosenthal has pointed out ("Diseases of the Nervous System," p. 408), the fact of lead-poisoning does not exclude the possibility of cerebral hemorrhage and true apoplexy.

Malarial poisoning may produce sudden coma closely resembling apoplexy. The history and residence of the patient should guide to a correct diagnosis. Malarial coma is usually preceded by other symptoms of malarial intoxication. The temperature of the body is above the normal from the commencement of the attack, while in apoplexy it is for some time depressed, and when it begins to rise it progressively increases, instead of remitting, as it does at the close of a paroxysm of malarial fever.

Opium-poisoning, with contracted pupils, livid features, perspiring skin, and utter unconsciousness, may be occasionally mistaken for apoplexy caused by hemorrhage into the pons. The normal or slightly elevated temperature, the absence of paralysis, and the retarded respiration immediately distinguish it. Pontine hemorrhage also determines the appearance of sugar and albumen in the urine, which is not the case after simple opium-poisoning.

Having thus differentiated the attack from all the foregoing possibilities, it may fairly be assumed that the case is genuinely apoplectic. It then becomes necessary to determine whether it is the result of a primary cause or of a secondary one, and hence to turn once more to the definition of apoplexy as "a sudden suspension of cerebral function caused by an internal lesion of the circulationary apparatus acting directly upon the brain," it is evident that the sudden seizure may originate in a number of different conditions. Hence the old classification: apoplexia nervosa, apoplexia serosa, apoplexia urinaria; and the modern subdivision, which there were no visible lesions of the brain-substance; the second included all cases of sudden unconsciousness with serous or dropical effusion within the cranium; the last included all cases of vascular rupture and extravasation of blood. Serous apoplexy is usually observed as a consequence of atrophy of the cerebral convolutions, with aneurysm without Blood. It is sufficiently rare to be almost wholly left out of consideration; yet its possibility should not be forgotten when the autopsy yields no other visible result. In the vast majority of cases, therefore, the probable causes of any given apoplectic seizure narrow themselves within two classes: cerebral hemorrhage caused by vascular rupture, and cerebral anemia caused by vascular spasm. This is a true truism. There is almost a certainty when coincident with heart disease, right-sided hemiplegia, and aphasia. The graver forms of apoplexy, with sudden onset, or rapid aggravation of severity, must be referred to hemorrhage.

Time and space will not permit me to discuss the particular causes of cerebral hemorrhage. Be it sufficient to remind the reader of the interesting researches of Charcot and Bouchard, regarding the aneurismal processes which finally lead to rupture of the cerebral vessels. The pages of Wernicke give ample information relative to the anatomical and pathological disturbances which condition the seizure itself. Let me hasten to a consideration of the medical treatment required in the management of apoplexy.

The ancient and orthodox treatment of apoplexy is admirably set forth in the following extract from the diary of John Evelyn, describing the death of King Charles the Second:

"I went to London, hearing his Majesty had been the Monday before (2 Feb.) surpriz'd in his bed-chamber with an apoplexy, and the temperature in ordinary intoxication than in apoplexy, and the presence of hemiplegia would be almost decisive in favor of apoplexy."
moment, which might have been of direful consequence, there being nobody else present with the King save this Doctor and one more, as I am assured. It was a mark of the extraordinary dexterity, resolution, and presence of mind in the Doctor, to let him bleed in the very paroxysms, and thus keep the symptoms from fastening on those vessels which regularly should have been done, and for want of which he must have a regular pardon, as they tell me. This resuscited his Majesty for the instant, but it was only a short reprieve. He still complained, and was relapsing, often fainting, with sometimes epileptic symptoms, till Wednesday, for which he was cupped, let bleed in both jugulars, had both vomit and purges, which so relieved him that on Thursday hopes of recovery were signified in the public Gazette, but that day, about noon, the physicians thought him feaverish. This they seemed glad of, as being more easily allay'd and methodically dealt with than his former fits; so as they prescribed the famous Jesuits powder: but it made him worse, and some of the Doctors who were present did not think it a fever, but the effect of his frequent bleeding and other strong operations upon him by their head, so that probably the powder might stop the circulation and renew his former fits which now made him very weak. Thus he pass'd Thursday night with great difficulty, being complaining of a pain in his side, they drew 12 ounces more. When he was on the point of waking on Friday, and it gave him relief, but it did not continue, for being now in much pain, and struggling for breath, he lay dozing, and after some conflicts, the physicians despairing of him, he gave up the ghost at half an hour after eleven in the morning, being 6 Feb. 1655, in the 36th year of his reign, and 54th of his age.

Such were the methods which delighted our forefathers, and the tradition of their efficacy is by no means yet extinct. But in these days we rarely resort to extreme measures. No one who could recognize or suspect the presence of an embolus or a thrombus in one of the cerebral vessels, would now be likely to expect their removal by any kind of sanguineous emission. In that class of cases the treatment must be of the most negative and expectant character, addressing itself to the general care of the patient, with comparatively little reference to local lesions in the brain. If any special medication is employed, it should be limited to the administration of carbonic acid, ammonia and chlorate of potassium—remedies designed to stimulate the circulation and to stimulate the action of the kidneys. Theoretically useful in cases of interrupted circulation, it is doubtful whether the final result can be appreciably modified by their use.

The treatment of serious apoplexy is in like manner to be conducted with reference to the remote causes of the disorder rather than to the state of cerebral function. The difficulty which attends the ant-emortem recognition of the forms of the so-called "simple apoplexy" must always render it impossible to formulate any specific mode of treatment. The symptoms and circumstances of each case must dictate the proper line of procedure.

Very similar must be the conduct of the physician in the case of extra-cranial hemorrhage. Bleeding has not yet been established as a recognized mode of arrest of extra-cranial hemorrhage, and there is no reason to suppose that it can be any more effectual when the lacerated vessel is within the brain. The supposed relief of blood-pressure, for which bleeding has been recommended, is of so transient a character that its advantages cannot compensate the danger. It is rarely a permanent arrest of fluids of the body. Physiological experiment ("Foster's Physiology," book i., chap. iv., sec. 7), shows that when an animal is bled from an open vessel the pressure in the other vascular channels sinks only during the flow of blood, and speedily recovers its normal height, unless the amount of blood removed equals at least three per cent. of the body-weight. This would necessitate bleeding to the extent of from three to six pounds in the case of an adult patient. But it is further observed, when this proportion has been reached, that great and permanent depression, frequently associated with anæmic convulsions, is suddenly developed. In the light of these experimental results the case of Charles II. forms one of the most instructive exceptions, the opinion of the time was that recovery was certain.

It does not follow, however, that medical art is powerless during the apoplectic seizure. In congestive forms of the attack, when, probably, no vessel has actually given way, but when the vascular network of the brain is inundated with blood, when the face is flushed and the bounding pulse indicates a vigorous determination toward the head, great benefit may be expected from local depletions. The application of leeches to the anus, or behind the ears, and upon the temples, produces great reduction of the local fluxion by its effect upon the vaso-motor mechanism. Ergot is theoretically useful for the same purpose, but there is no evidence to show that it is ever effectual after actual rupture has occurred. The course of the blood-current may also be largely diverted from the brain by the establishment of centres of attraction in remote quarters of the body. Hence the undoubted value of sinapis applied to the lower extremities. Hence the happy effects sometimes witnessed after the administration of croton-oil and other active cathartics. The application of ice about the head is useful, the cold diminishes the amount of blood in the extremities and limits the figure, i.e., after the attack has culminated and the period of local inflammation in the vicinity of the ruptured vessel has arrived.

It is after the period of apoplectic seizure that the intervention of the physician is most useful. If death does not close the case, the patient then enters upon a long series of more or less partial convulsions, diversified by the development of various phenomena dependent upon the local injuries sustained by the brain. Adequate consideration of the connection between these phenomena and the particular location of such injuries and alterations would lead too far into the fascinating field of investigation connected with the subject of "cerebral localization." It must suffice to recall the fact that some form of paralysis is the usual result of apoplexy. The intensity and the duration of such paralysis will depend largely upon the extent of the injury within the brain, and upon the completeness of its subsequent repair. For this reason it becomes highly important to care for the general health and nutrition of the patient. The bowels must be kept open and the bladder and bowels must be noted; all symptoms of inflammation should be opposed as they arise. In certain serious cases it is remarked that joint-affections, analogous to those sometimes witnessed in locomotor ataxia, and bed-sores appear shortly after the attack. These are developed as a consequence of that profound shock to the nutritive process which is dependent upon grave lesions of the nervous centres and their connections with the periphery. The bed-sores are always situated upon the paralyzed side of the body, and usually upon the buttock, in this respect differing from the bed-sores of myelitis, which are placed upon the sacral region, so as to involve symmetrically the parts on either side of the line.

The bed-sores may appear very soon after the initial seizure—in a few hours—two or three days at the most, perhaps—are sufficient to demonstrate the commencement of necrosis. The soft parts are rapidly disintegrated, precisely as in cases of spinal paralysis, but the subsequent processes of gangrene, toxic infection, pyaemia, and lingering exhaustion which succeed, are rarely so prolonged as to admit of a parallel with the tedious evolution of a spinal bed-sore. Speedy death is the almost inevitable result of these cases.

The period of convalescence after an apoplectic attack affords a favorable opportunity for the exercise of medical skill. During the return of sensibility, after the inflammatory stage has passed, while the power of motion is returning to the lower limb, and the upper ex-
trenity is exhibiting evidence of approaching mortility, the question of possible contracture becomes important. Since these late contractures are the consequence of descending degeneration of the pyramidal tract, it is necessary to observe with care the condition of that portion of the cerebro-spinal apparatus. The first symptoms of disorders in the case revealed from four to six weeks after the original apoplectic attack. Careful exploration of the joint-reflexes, at the elbow, wrist, knee, and ankle gives no evidence of difference between the two halves of the bodily frame so long as degeneration is restricted to the original seat of injury in the brain. But when the degenerative process invades the anterior portions of the spinal column, and the crus cerebri, the reflexes of the paralyzed side become exaggerated. To this symptom of evil omen are soon added the evidences of a progressive deformity which gradually increase until the well-known features of "late rigidity" have been fully developed. For this unfortunate result there is little relief to be obtained from medical art. Paralysis of the extensor muscles has been extensively employed for the purpose of invigorating the natural opponents of the contracting flexors of the limbs, but without any satisfactory results. In fact, as Erb remarks (von Ziemssen's "Handbuch der allgemeinen Therapie," III. Band) concerning the use of electricity and similar agents, all that can be done is to decide how much benefit may or may not be secured by its employment. Hence it is impossible to reproach the physician who does not subject a recent case of apoplexy to electrical treatment. During the earlier stage of recovery no form of electrical current is admissible, but after the expiration of a few weeks some advantage may be derived from its use. Certain enthusiasts advocate the application of the galvanic current through the head as soon as it is evident that the patient may recover. Others, dreading the undoubted possibility of thus exciting the cerebral circulation to a degree provocative of renewed hemorrhage, counsel a delay of at least six months. Erb wisely chooses a middle course. Scarcely before the end of the first month after apoplexy would he commence the use of electricity, and then with great caution, guided by its effects upon the apparatus of circulation. Weak galvanic currents from five or six cups may be applied to the head and neck, in order to promote absorption of the clot, and the cure of inflammatory processes in its vicinity. The faradie current may be used in addition, the passage of the current through the enfeebled muscles to their enfeebled state, through voluntary exercise. Beyond this nothing can be expected from electro-therapeutics. It is very probable that the result of treatment by massage is fully equal to the effect of electricity. But electricity possesses the advantage that it must ever remain the property of the physician, while massage is generally relegated to less intelligent hands.

Great attention should be directed to the general health of the patient. Lithemic and rheumatic subjects should be treated with special reference to their peculiar diatheses. The hemorrhoidal diathesis deserves particular consideration, for the sudden suppression of a hemorrhoidal flux has not infrequently been followed by an apoplectic attack. In all cases which exhibit a tendency of blood to the head the bowels should be kept freely open. The various preparations of buckthorn, cascara cordial, etc., are usually to be preferred on account of their admirable effect upon the digestive organs. But if it be desired to excite a derivative process in the pelvic region, the aloeotic laxatives should be selected. The most powerful laxative aid is the Hunyadi János, Carlsbad, Rácóczy, and the stronger Saratoga waters, produce excellent effects when constipation is associated with disorder of the liver. Many chronic headaches may thus be completely cured.

The matter of diet is not a subject for indifference. A large proportion of the cases of apoplexy are associated with obesity, and are the direct result of a fatty de-generation of the vascular walls. Great accumulation of fat, moreover, produces mechanical obstruction both of the organs of circulation and of respiration. Imperfect nutrition and incomplete aeration of the tissues follow as direct consequence, leading to various forms of degeneration in different parts of the body. In cachectic subjects, therefore, should not be subjected to use alcohol in any way, and their consumption of fats and starch should be quite moderate. The amount of food should be restricted to the absolute necessities of the patient, and its quality should accord with the standard established by physiological research. A complete dissertation upon such a subject would lead me too far. Suffice it to remind the reader that the diet of a rheumatic or gouty patient should be made to differ from that of a victim of fatty degeneration or of scorbatic cachexia. All such people are liable to apoplexy, but the mode of its production would probably be different in each class. Finally, it appears that while the efforts of the physician must be restricted within comparatively narrow limits, when he undertakes the care of an apoplectic patient his therapeutic measures must be wisely selected and decidedly energetic. They may be thus summarized:

1. During the apoplectic attack.——The activity of treatment should be inversely as the severity and danger of the case. Complete depilation, for instance, should not be done. Milder forms are to be treated with croton-oil, leeches about the temples, behind the ears, and at the anus. When leeches cannot be procured, and in cases of simple hyperemia, wet cups should be applied to the back of the neck and between the shoulders. General bleeding only advisable when the right side of the heart is congested, not when there is true hemorrhage. Adhesive lint and distention of the veins about the head and neck. The bladder should be watched, and the catheter must be introduced if the urine is retained.

11. After the attack, and during the period of inflammation or softening in the neighborhood of the cerebral lesion.——The bowels must be kept open, preferably with mercurial and saline laxatives. Chlorate of potassium or iodide of potassium may be given to stimulate the kidneys. Tincture of aconite is an excellent agent for reduction of the pulse during the inflammatory fever. If this be insufficient to obviate cerebral hyperemia, recourse may be had to electricity, massage, exposure to the open air, diathetic and dietetic treatment, with especial attention to general hygiene.

Somewhat unique.——Dr. George E. Brickett sends us the following: "T. S——, of Augusta, last Saturday evening, broiled and shelled out into a bowl one peck of clams. While shaking a glass pepper-box over the bowl it dropped from his hand, striking on the edge of the bowl, breaking into several pieces, all of which he supposed fell on the table. Mr. S—— is very fond of clams, and being very hungry swallowed them whole by the big spoonful. With one large mouthful he said he felt 'something hard going down his windpipe,' but kept on and finished his peck. He felt well all day Sunday, worked on the road Monday and Tuesday. Wednesday morning after stool he felt something prick near the anus, he put his finger up and felt something hard. He said when he came to my office that he could feel either a corn-shell or a piece of pepper-box in his fundament. I examined him and removed from his rectum a round piece of glass three-fourths of an inch in diameter, with rough edges. The only inconvenience experienced in this case was in swallowing something hard and the sensation of prickling in the rectum. The glass passed from the stomach to the rectum in sixty hours, without producing the least disturbance."
THE DIFFERENTIAL DIAGNOSIS OF MALARIAL FEVERS.

By SIMON BARUCH, M.D.,
NEW YORK.

The differential diagnosis of malarial fevers may now be more briefly concluded by reference to those forms of fever which simulate them.

First among this group stands the so-called typho-malarial fever. This much-abused term was originated, as is well known, by Dr. J. J. Woodward, of the United States Army, and has served well and faithfully for many years as a shield and refuge in the diagnosis of obscure forms of fever. What usefulness of those cases can be claimed to offset this detrimental influence, I fail to see. The author, who is justly respected as an able and accomplished scholar and physician, does not claim that typho-malarial fever is a specific type of fever, and he divides it into three groups: First, those cases in which malarial phenomena predominate, and which, even when typhoid symptoms were most pronounced, lacked the most striking characteristics of typhoid fever, and a large proportion of which terminated favorably especially because quinine was so freely used. In these cases "convalescence was frequently marked by regular paroxysms of ague." The autopsies which were made showed no other lesion than intestinal catarrh. Second, group in which typhoid symptoms predominated. These cases can be claimed to offset this influence began like it ran their course like it refused to be cut short by quinine; after death presented characteristic lesions of Peyer's glands. Third group formed by scurbutic cases. The author has here drawn in the first group the adynamic remittent fever, to which I have referred, and which he acknowledges has been long ago described by Dr. John H. Law. It is common to others, a purely malarial fever yielding to quinine. The depressing influences of camp life in an inhospitable region, picket duty in the presence of an active foe, and the terrible strain due to repeated skirmishes, lent this adynamic type to the remittent and intermittent fever of the Chickamaugy swamps and elsewhere. Moreover, the causes of typhoid fever were also in active operation, as is testified by the enormous number of cases of this disease. This was not the assumption of the livery of abdominal typhus by malarial fever, nor vice versa, but an engraving of the new disease upon the pre-existing intermittent or remittent. This is evident from the author's own description of the second group, which is a correct picture of extended state of the malarial question this is a consumption. That the term has proved unfortunate is reluctantly admitted by the author, when he says: "There has been, I admit, some indiscriminate use of the term, which is well calculated to bring it into discredit. I have myself known it to be erroneously applied to simple typhoid fever;" etc. "I think I have observed also a tendency in many quarters to bestow the term upon almost any obscure febrile affection which afforded diagnostic difficulty." A careful discrimination of the symptoms and due regard to those almost pathognomonic signs of true malarial fever will relegate these so-called typho-malarial cases to their proper position, and lead to a more satisfactory diagnosis and treatment. In the present confused state of the malarial question this is a consumption devotedly to be wished, and to be hastened by the abolition of the term "typho-malarial" from our nosology.

Typhoid fever, or enteric fever, presents in all its stages striking differences, which enable the careful observer to discriminate between this disease and malarial remittent fever. The presence of results, its adynamia is characterized by suddenness and rapidity of development; even if the latter is not the case, careful inquiry will elicit the fact that the precursory malaise bore evi-
typhus or typhoid than to malarial fever. One of the chief etiological factors of this disease is the poison arising from sewers, that prototype of the true malarial poison, which is not like the latter of telluric origin, but which is the resultant of decomposition of the excreta and secreta of the human body.

Richardson* says: "The disease *par excellence* derived from the sewer is that continued fever which is induced by the natural atmosphere of the sewer, by the inorganic products of organic decomposition, of which sulphuretted hydrogen plays the leading part." Gerhard has also described a fever of non-specific type, viz., neither typhus nor typhoid. "Instances of ordinary malaise and severe gastric disturbances culminating in gastric fever, or even enteric fever of the non-specific type, wanted a distinct classification of the glandular tissue and the excreta of the body, and not presenting the typical rose-spots—the 'febrilitates' without a puncture' mark of true typhoid, were adduced by William Budd in proof of the mischief that might be wrought in a household by bad sanitary arrangements."**

G. B. Wood** says: "A low fever, somewhat of the typhus character, is developed, though infinitely less destructive, in some cases of typhoid fever, in the debilitated condition of the patient, a depressed state of his blood, from bad living, an exposure for some time to depressing influences, as of certain epidemics, exhalation from privies, etc., may account for their dynamic character. In some instances the disease appears to assume the intermittent form."

Thus defined for the purpose of defending the writer from any desire to create an unnecessary addition to our nosology. The term idio-miasmatic pyrexia was introduced, as has been stated above, by Dr. Edward Miller, and was used (as I am informed by a gentleman who attended his lectures) by the late Professor Jos. Mather Smith to designate all those fevers due to effluvia emanating from the human body, in contradistinction to keino-miasmatic pyrexia, due to causes foreign or external.

As the term malaria may really be applied to all influences connected with bad air, and thus be regarded as the chief etiological factor of all contagious and infectious diseases, it is important to adopt another term for all those emanations which arise from human excreta and secreta furnished by sewers, overcrowded dwellings, schools, hotels, flats, etc. The term "malaria" is too firmly established to be now expunged. It would, therefore, be the part of prudence to avoid attacking it and the part of wisdom to establish the term "ido-miasm" to designate all those (animal) poisons, which produce the symptoms of malaria, which are now erroneously charged to malaria. The term miasm does not offer a sufficiently clear distinction, because it has hitherto been frequently applied to paludal emanations, and has thus become interchangeable with the term "malaria."

It would indeed be a bootless hair-splitting to enforce a distinction between malarial fever and ido-miasmatic fever, were it not that important therapeutic considerations are involved. The safety of the patient depends upon careful diagnosis of true malarial fever from that form of idio-miasmatic fever which doubtless now figures quite largely in the Board of Health Reports as "remitting fever." In the one case we have a true specific in quinine, a remedy which has no peer in our entire therapeutic armamentarium; in the other we are met by indications, totally different, which are based upon a correct appreciation of the causes of the malady and must be fulfilled by efforts to guide the disease to a favorable termination rather than to abort it. In this paper being strictly clinical, I refrain from entering upon the discussion of the subject of the etiology of idio-miasmatic fever, and content myself with this brief reference, which is intended to be merely suggestive.

Physicians daily encounter fevers of a continued type which cannot be properly classed with typhus, typhoid, or relapsing fever, and which, though simulating malarial remittent fever, may be as readily differentiated from this as from the other forms of fever. When occurring in children it has been termed, infantile remittent; in adults, catarhal fever, common continued fever, irritative, gastric, or mild typhoid fever, etc. The disease is ushered in by general malaise of brief duration; there is no decided chill, but often a shivering, alternating with flushes of heat. These bring the patient to bed, or induce him to drag along for a few days ere he succumbs. Appetite is quickly lost; there is not a violent thirst, but a craving for cool drinks; there is frequent retching, often loathing of food; there is no severe headache, but a throbbing or constriction within and around the head. Pulse is normal in quality, but is accelerated, ninety to one hundred in mild cases. The bowels are normal, sometimes constipated; kidneys act freely, urine being high-colored and depositing urates. There are no prostration or delirium, no sleeplessness, not present, no laconic character. In some instances the disease appears to assume the intermittent form."

The tongue is covered with a white coating—there is a viscid secretion upon it; it is fleshy, soft, and receives readily the impression of the teeth. There are other symptoms of gastric and duodenal catarrh in many cases; distaste for food, unpleasant taste in mouth, eructation, epigastric oppression after aliments, sense of fulness and tympanitic distention of the upper abdominal region in advanced or severe cases there is sometimes vomiting, with decided evidences of active gastric irritation. These symptoms would indicate that the upper alimentary tract is involved in idio-miasmatic fever, in contradistinction to true enteric fever, in which the chief evidences of pathological changes are furnished by the lower portion. Not having had opportunities for autopsies, I am unable to corroborate by pathological evidences this view, derived from the clinical features. The duration of this type of fever is from five to fifteen days; there is no critical discharge or secretion; but it terminates by lysis, according to the intensity of the impregnation, presumably in a long or shorter period.

From true malarial remittent this disease may be distinguished by the absence of regular morning remission or decided remission at any time; by absence of large temperature excursions, and especially of the high range attained by the former; by the absence of the invariable

---

* London Lancet (editorial), June 10, 1886.
thirst, intense headache, and other symptoms referred to as the delirium of remittent fever. From typhoid fever it is not so readily distinguished, especially when adynamic symptoms are marked, but in the large preponderance of cases the absence of decided adynamia, rose spots, regular temperature curves, etc., will eliminate typhoid fever from the diagnostic field. I have no doubt that many cases of idio-miasmatic fever are now reported under the heading of common continued, gastric, and typhoid fever; but as malaria is the fashionable etiological factor at the present time it probably predominates largely in bearing the title of this fever.

The prognosis of idio-miasmatic fever is favorable, unless complicated by visceral troubles or attacking feeble subjects. Not unlike its prototype, malarial remittent, a recognition of its true type is of vital importance and forms an important element in the prognosis. Many cases are complicated with bronchial trouble, others with follicular tonsillitis and pharyngitis, which, owing to adynamic symptoms are not rarely diagnosed as diphtheria.

The green idio-miasmatic fever in this city diagnosed as typhoid fever, but its brief duration, absence of abdominal symptoms, rose spots, etc., convinced the attendant of his error, while patient and friends congratulated themselves on having escaped in twelve days from a dreaded malady which usually lasts many weeks. In another, but sadder case this fever was diagnosed when tuberculous meningitis was really impending. In conjunction with Dr. Osborn, and the diagnostic acumen, I treated a boy, ten years old, who presented the characteristic symptoms of idio-miasmatic fever; five days before dissolution tuberculous meningitis developed. There had been no headache, no vomiting, in fact absolutely not a single suspicious symptom of this fatal malady, during two weeks of our attendance prior to the first symptoms of meningitis. When another consultant and the diagnosis was corroborated by an ophthalmoscopic examination, which I succeeded in obtaining, after several failures, on the day before his death. The optic disk was hazy, its outline edematous; the vessels swollen and tortuous, and several roundish elevations of a light pink hue were plainly visible near the macula lutea.

Purulent accumulations within or around the viscera give rise to fever of a decidedly remittent type, which is often fatal and doubtless serves to swell the mortality statistics of malarial remittent fever. Many of these cases are obscure, but they offer typical stages of cold, pyrexia, perspiration, and remission. Few physicians of experience are unacquainted with the experience of fever.

Perinephritic abscess, for instance, is not rarely free from well-marked local symptoms. The disease is almost invariably ushered in by a rigor or shivering, succeeded by febrile reaction, temperature rising to 104° or 105° and continuing until perspiration ensues, and remission often occurs during the morning hours. There are other symptoms characteristic of malarial remittent, as jaundice of the skin, furled tongue, great thirst, nausea, and constipation. Remission may occur several times ere the diagnosis is rendered clear by local evidences and the inefficacy of quinine to check the paroxysms.

Hepatic abscess presents frequently another source of diagnostic error. It is a well-known fact that purulent accumulation in the liver parenchyma may occur without giving rise to pronounced local disturbance. Fever of remittent type, presenting the whole picture of rigor, heat, and sweat, recurring day after day, mark the development of hepatic abscess. This is not a disease of tropical climates only. Bartholow1 claims that "abscess of the liver is very common in the great interior valley of North America, along the Mississippi and its tributaries."

Chaillet2 states that it is a remarkable fact that out of one hundred and fifty post-mortems made in one year in the dissecting-rooms of the New Orleans Medical College, there were more abscesses of the liver found than were reported in the entire annual mortuary list of New Orleans.

Thus the inference is deducible, that deaths from hepatic abscess are very frequently charged to remittent fever, which disease is so closely simulated by its febrile symptoms. The same error is probably sometimes committed in New York City, which is the great centre towards which travellers from all climes gravitate in this country, and whose shipping interests furnish an enormous number of people from tropical and semi-tropical countries.

May not these furnish a portion of the deaths reported from remittent fever, without recourse to malaria as an etiological or lethal factor?

Refluxing fever so neatly imitates the periodic remissions and high temperatures of a true malarial remittent that it presents some difficulty of diagnosis, especially as there are often nausea, vomiting, muscular pains, hæmorrhagic and splenic enlargements. Its recurrence, however, at certain periods after entire cessation, its history and etiology, and its invulnerability by quinine, will guard against erroneous attribution.

Ulcerative endocarditis and arteritis is mentioned by Murchison3 as liable to lead to error in diagnosis. Now and then it gives rise to intermittent fever, occurring daily for weeks and months, and yet no evidences of pus can be detected in life or death. In many cases the fever is doubtless associated with formation of embolic masses in the spleen. In others, no such cause can be discovered. The paroxysms are characterized by elevation of temperature, 103° or higher, followed by perspiration, and occasionally it is ushered in by severe chills. "You have already seen," he says, "a case of mimal disease with fever answering this description, and I attended a private patient with disease of the aortic valve. This fever, which lasted to the day of death, had daily paroxysms of fever, commencing with a definite rigor, and always ending in copious perspiration, and where the friends were so satisfied that the fever was ague that they insisted on large doses of quinine."

The lectures of Murchison abound in illustrations of diseases which may be confounded with malarial fever. Lymphadenoma, erysipelitic fever, and hepatic fever are referred to in this connection. The latter is due to gall-stones which block the bile-duct, and is characterized by regular intermittent fever. Some patients have twenty or thirty attacks, which are often postponed, but not prevented by quinine.

Acute tuberculosis sometimes presents symptoms which, owing to the regularity of the morning remission and afternoon exacerbation, may mislead the diagnostican. Errors of this kind would seem to me improbable, but Murchison says that he has repeatedly been consulted in cases of this kind on the supposition that the patient was suffering from enteric or malarial fever, and where on the one hand the persistence of the fever over a month, and on the other the failure to obtain clinical evidence of the paroxysm, had thrown doubt on the original diagnosis and led to consultation. The paroxysms of fever occur chiefly toward night, temperature rising to 102°, 103°, or higher, followed by night-sweats. Rigors are rare. In the morning and during the greater part of the day the temperature may be normal. After a time the real nature of the trouble is revealed by local signs in the apex of one lung, or supervision of symptoms of chronic peritonitis or acute meningitis.

In my personal experience there has been little difficulty in distinguishing acute tuberculosis from malarial fever, inasmuch as the short pyrexia followed by prolonged and exhausting perspiration,1 the former differing strikingly from the course of the latter, and the paroxysms usually occur in the more advanced stages, when local evidences are not wanting to render the diagnosis

3 London Lancet, 1879, i., 609.
perfectly clear. The diagnosis of the early, stages of acute tuberculosis from typhoid or idi-o-miasmatic fever is more difficult, because the latter is characterized by a more continuous type of fever, not succeeded by perspiration. The case of tubercular meningitis, cited above, when discussing the diagnosis of idi-o-miasmatic fever, illustrates this difficulty.

PUERPERAL SEPTICÆMIA AND CONSTANT IRRIGATION OF UTERUS.

By TALBOT JONES, M.D.,
ST. PAUL, MINN.

The interesting and highly important paper on puerperal septicemia read by Dr. T. Gaillard Thomas before the Academy of Medicine on December 6, 1883, which was published in the last Record deserves and will command the thoughtful attention of all progressive physicians, both on account of its distinguished author, and the inherent importance of the subject itself.

The frequency of puerperal septicemia, its gravity, the anxiety it always occasions the conscientious accoucheur, and the great divergence of opinion held regarding its pathology and treatment, invests the subject with a peculiar and painful interest to the general practitioner, and the timely contribution of Dr. Thomas will doubtless awaken wide hearing. The interest his paper awakened is shown in the debate that followed, which, upon motion of the president, was adjourned to the first meeting in February. We cannot anticipate the views that will then be expressed, though the debate will likely prove a memorable one.

In view of this approaching discussion the time is ripe, and the professional mind will be prepared for a report of clinical cases; for after all clinical observation is a vehm-gericht from whose sentences there is no appeal. I therefore venture to report three cases of puerperal septicemia treated by constant irrigation of the uterus, notwithstanding it is a method which Dr. Thomas terms a "delusion and a snare."

It was resorted to only after a faithful though unsuccessful trial by intermittent intra-uterine injections, which depressed the temperature for a time only, and not permanently. Dr. Thomas, in his condemnation of constant irrigation of the puerperal uterus, leaves us in doubt whether this opinion is based upon a sad personal experience, or is rather a method of inferential reasoning which so far as I know has not been tried in this country. In one case the patient had no complaint of acidity, and the reflux of the washings was comparatively small.

"Be this as it may, I feel firmly convinced that my patients' lives were saved by the treatment that Dr. Thomas condemns, and would have been lost by the plan he approves, for in each case the irrigation was tried only as a last resort, and after intra-uterine injections had failed to accomplish the object sought. This paper is not to advocate constant irrigation of the puerperal womb, but merely to report three clinical cases, and is written rather as an appeal to the profession to place on record their clinical experience, to report their successes and failures alike, when some one in the future may be enabled out of the sum of the knowledge thus obtained, to formulate the proper treatment to be pursued in those morbid processes embraced under the generic term of puerperal fever.

Though not sanctioned by Dr. Thomas, this treatment, in appropriate cases, has a large following and undoubted acceptance in Germany and Italy, and according to published statistics its success has been conspicuous enough, especially in the case of labor, to Dr. Pasola, Annalia di Obstetricia. My cases are as follows:

CASE I.—Mrs. M., aged thirty-six, German, in the middle walks of life, living under fairly good surroundings, the mother of three children, the oldest being fourteen, was delivered of a healthy girl after a moderately severe labor. The uterus contracted well, though there was considerable after-pain. Thirty-six hours subsequent to delivery she had a severe chill, suppression of the lochia, headache, vomiting, and pain. Temperature, 104°F., which gradually rose to 105°F., on the third day; pulse, 120. The lower abdomen became tympanitic and extremely tender to the touch, even the weight of the bedclothes causing severe pain. An examination showed no laceration of the cervix or abrasions of the vagina. Feeling sure that this complexus of symptoms was due to the decomposition of placental débris a Sims speculum was introduced and with a curet a bit of disintegrated placental tissue the size of a filbert was removed. Intra-uterine injections of a three per cent. solution of warm carbolic acid were employed every three hours; the pain relieved by high-grain morphia suppositories and twenty-grain doses of quinia given according to circumstances, and hot flax-seed poultices applied over the abdomen. Later along all the symptoms increased in severity; the temperature rose to 105°F., the pulse to 140 and was weak and thready; a mild delirium supervened, her face wore a pinched expression, and the whole body was bathed in profuse perspiration. At this juncture, when her life was well-nigh despaired of, constant irrigation of the uterus was decided upon. A Knott's double-current catheter was attached to a fountain syringe having a stop-cock, which regulated the flow of the liquid. Her hips were elevated and placed on a partially inflated rubber pillow. With the cloth and the mattress of the bed a hole was made to permit the return fluid from the uterus to be received into a vessel under the bed. The fountain syringe could be raised or lowered on the wall, and by this means the force of the stream entering the uterus regulated. The finger introduced up to the ring of Band was applied to the endometrium, which readily separated from the fundus. The fluid used was a three per cent. solution of carbolic acid at a temperature of 100°F. The syringe was elevated, the stop-cock turned slightly at first, and the interior of the womb irrigated. The operation was watched narrowly, though no untoward complication arose. In twelve hours the patient's temperature was depressed to 103°F., and twenty-four hours later to 101°F., above which point it never subsequently rose.

CASE II.—A primipara, aged twenty-two, in comfortable circumstances, was seized on the third day after a severe instrumental labor with a chill, and three hours after her temperature registered 104°F., pulse, 135. The disease pursued much the same course as in the preceding case, the patient enduring the same or a less severe degree of symptoms. Internal medication was the same as that employed in the first case. This patient's temperature was depressed by intra-uterine injections to the extent of 2°F., 3°F., and once as much as 5°F., but invariably rose to the original fever point in the course of one hour after the injection. The failure to keep her temperature permanently within bounds induced me to again resort to constant irrigation, which was continued for sixty hours, when the thermometer registered 102°F.

She made a good recovery.

CASE III. was a French woman, a multypara, residing on the flats of West St. Paul, under bad hygienic surroundings. I was called to attend her for a threatened miscarriage at the sixth month. She could assign no cause for this; had received no fall or strain, and stoutly denied all criminality. She said she had felt no "life" for some time. This, together with the fact that she experienced chilliness, languor, a bad taste in the mouth, and a weight as from a foreign body, suggested that the child was dead—an opinion that was strengthened when a careful inspection disclosed that a death rattle could be heard, and through the open cervix the frontal bones were found loose and movable within the integument. Ergot was given, which produced strong, though not sufficiently powerful pains to enable the uterus to empty itself, and the fetus had to be extracted by the hand
twenty-four hours later, and was found dead and decomposed. The discharges from the uterus were extremely offensive from the nature of the discharge, which was 105° before delivery, after it rose rapidly, and a maximum of 106° was touched in twenty-four hours. Intra-uterine injections of warm carbolized water were employed every three hours, and in addition, three injections a day were made to the interior of the organ, of a solution of 10% glycerine, 1 to 15. Her temperature was always temporarily depressed by each injection, but again rose to the original point in an hour after each operation. The internal treatment by drugs was the same as that employed in the first cases. The patient soon passed into a state of imminent peril, with high fever (106°), mild delirium, and a feeble and rapid pulse, denoting a failing nature. Constant irrigation was again resorted to, and though the fever defervescence was not marked for the first six hours, subsequently the decline in temperature was slow, but progressive, until 102.5° was touched, when the patient's appearance denoted a marked improvement. She made a slow but comparatively good recovery, with some sub-involution of the uterus.

Salicylic Acid as an Application to Epitheliomatous Growths.—Recently at St. Bartholomew's Hospital, during a consultation on a case of rapidly growing epitheliomatous vegetations springing from the floor of a rodent ulcer, Mr. Thomas Smith advised Mr. Howard Marsh, under whose care the patient was, to use a saturated solution of salicylic acid as a local application. Mr. Smith said that, some time ago, he had been induced to make use of this remedy in the treatment of simple papillomata, and the result had been so favorable that he was led to apply it to epitheliomatous cases also. In the first case, which had now been under observation for some time, the application was entirely successful, the epitheliomatous growth having been entirely destroyed in two or three weeks. It is said that Dr. Thin has also had favorable experience of the remedy.

A New Treatment for Sleeplessness.—Dr. J. Mortimer Granville recommends his percursor as a remedy for insomnia and says that it rarely fails. He applies it along the dorsal spine, or, if this fails, over the left zygo-

THE MEDICAL RECORD.

AN INTERESTING HISTORY OF INFECTION OF A FAMILY BY AN INFANT HEReditarily SYPHILITIC.

By G. FRANK Lyston, M.D.,
LECTURER ON GENITO-URINARY AND VENEREAL DISEASES, COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO, ILL.

A short time since I was consulted by a gentleman in regard to the cases of his wife and eldest daughter, in both of which appeared investigation had been suffering from various manifestations of syphilis for the last four years, having been under various systems of treatment at different periods during that time. He himself had also suffered from mild symptoms of the same disease, but at the time of his consulting me he expressed himself as cured. The history of contagion elicited in these cases, and verified by the physician who had been the family attendant, was so interesting that I have thought it worthy of publication. In 1877 one of this gentleman's daughters was married to a dissolute fellow, whose views regarding his marital obligations were of a very lax nature, and who, shortly after marriage, and in the sixth month of his wife's pregnancy, contracted general syphilis by chance. During the course of these weeks—probably during the seventh month of utero-gestation, reckoning from the average incubative period of syphilis—his wife developed primary syphilis. At term, an apparently healthy living child was born, and the mother developed in a few weeks active secondary syphilis, which subsequently ran a chronic course, terminating in stillbirth. The chance.

Dr. F. A. Dunsmoor reported to the Minnesota State Medical Society, 1883, a case of death occurring during irrigation. The patient, after a normal labor, had a chill on the second day, a rise in temperature to 104°, and the usual symptoms of septicemia. On the third morning, when the irrigation was progressing, the patient remarked, "I hear such strange noises in my head," and immediately expired. How he performed the irrigation is not stated. He thinks death occurred as the result of an embolus, or else to the solution entering an open sinus. In my own cases at no time did symptoms arise denoting carbolic acid poisoning. The dangers from irrigating the perineal uterus are stated to be rigor, shock, entrance of air into the open uterine sinuses, or of the liquid into the peritoneal cavity, dislocation of a blood clot, etc.; but in my cases none of these complications were observed.

December 23, 1883.

Salicylic Acid as an Application to Epitheliomatous Growths.—Recently at St. Bartholomew's Hospital (British Medical Journal), during a consultation on a case of rapidly growing epitheliomatous vegetations springing from the floor of a rodent ulcer, Mr. Thomas Smith advised Mr. Howard Marsh, under whose care the patient was, to use a saturated solution of salicylic acid as a local application. Mr. Smith said that, some time ago, he had been induced to make use of this remedy in the treatment of simple papillomata, and the result had been so favorable that he was led to apply it to epitheliomatous cases also. In the first case, which had now been under observation for some time, the application was entirely successful, the epitheliomatous growth having been entirely destroyed in two or three weeks. It is said that Dr. Thin has also had favorable experience of the remedy.

A New Treatment for Sleeplessness.—Dr. J. Mortimer Granville recommends his percursor as a remedy for insomnia and says that it rarely fails. He applies it along the dorsal spine, or, if this fails, over the left zygoma near the root of the transverse process. Fine delicate vibrations are employed for five or ten minutes.—British Medical Journal.
its death at two years is not conclusive proof that it was not syphilitic, although it is usual for some manifestation of the disease to appear in the first few weeks or months. Late manifestations of hereditary syphilis are not unfamiliar."

Hutchinson first advanced the idea that the law of Abram Colles, viz., "that the hereditarily syphilitic infant cannot infect its mother," and vice versa, depends upon an impression made by the disease upon either the maternal or foetal organism analogous to vaccination. Thus in case the mother be infected, the disease may expend its violence upon her and the child escape positive evidences of syphilis although protected from the disease in the future. The reverse might also hold true in case of infection of the child by the father direct, through the medium of the semen. The possibility of this is, as is well known, denied by many, and the question is certainly a difficult one to determine positively, inasmuch as syphilis in the female so frequently manifests itself by symptoms so slight as to be unnoticeable, and in many cases the mother of a child hereditarily syphilitic is undoubtedly the medium of infection, although she has never observed any symptoms of disease in herself and may never exhibit them subsequently, even though later research has shown that such cases of the father of the child may not receive the benefit of the doubt. There is no doubt in our own mind, however, as to the direct transmission of at least a faulty organization, or some condition of malnutrition (scrofula?) from a syphilitic father to his offspring in many instances, and indeed far oftener than we are led to suppose. Hutchinson's present practice of prescribing mercury and curarials for struma, may have had a better pathological basis than he himself realized. Certainly the results of iodine in struma are very suggestive. Assuming that the views of the authorities quoted as advocating the primarily local nature of syphilis to be correct, and that the first child was really perfectly healthy, its non-infection after birth may be explained aside from the law of Colles by the fact that there may have been at no time a coexistence of abrasion of the mucous membrane of the child's mouth and abrasion of the mother's nipples. Infection through the medium of the milk has, of course, been shown to be impossible by such investigators as Bassereau, Diday, Rollet, and Clerc.

Progress in Cremation.—Cable reports from Portugal state that it has been decreed that, in all the municipalities, cremation shall be compulsory each five years, and the bodies be publicly cremated.

M. Brouardel, in a report on cremation to the Paris Council of National Health, states that he considers cremation to be opposed to the interests of justice. Crime would rest undetected, and the wrongly accused could not be exonerated. During epidemics, the danger to public health would be increased rather than lessened by the practice of cremation, inasmuch as the different processes require longer personal contact than does simple burial. The Council has adopted M. Brouardel's views and voted against cremation. M. Köchlin-Schwartz, president of the Society of Cremation, has addressed to the prefect of police the following objections to M. Brouardel's statements: "After cremation, traces of mineral poison are detected in the ashes, and these are always preserved. Vegetable poisons would escape detection; but equally so after inhumation, when the body would be decomposed. In cases of cremation, personal contact is not more prolonged than in ordinary burial. The chief difference lies in the fact that in one hour the body is reduced by fire to ash, and by undergoing slow decomposition, and giving off pestilential miasmas to poison the neighboring population."

1 Vide Fournier, "Lectures on Late Hereditary Syphilis."
THE MEDICAL RECORD.

CURE OF BLEPHAROSPASMUS BY MASSAGE.—A woman, forty-five years of age, had suffered for ten years from tonic spasm of the left eyelid. As she would not consent to undergo operation, Dr. Abadie determined to attempt a cure by massage. After smearing the parts with vaseline, strong friction was made with the thumb over the orbicularis muscle, so as to press the skin and underlying tissues in an outward direction. The first sitting lasted six or seven minutes, the second ten minutes. The procedure was repeated daily for three weeks, when the affection was cured. A second case, of a year's standing, was cured in two weeks; but in a third case, of intermitent spasm of both lids, the treatment was unsuccessful. The author thinks that this procedure may be of value in cases of nocturnal spasm of the lids—meaning by this term to express a condition from which many persons suffer, who, on awaking in the night or in the morning, are at first unable to open the eyes, being obliged to separate the lids with some force by the fingers.—Schmidt's Jahrbücher, October 17, 1883.

TREATMENT OF ULCERS BY THE SUBCARBONATE OF IRON.—Dr. Maison regards subcarbonate of iron as the best remedy for the local treatment of ulcers of various kinds, even those of syphilitic origin. The mode of application is as follows: The surface of the ulcer is first washed with carbolized water and then dusted thickly with powdered subcarbonate of iron, and over this is put a starch poultice. The poultice is usually changed twice a day. The healing process is very rapid, and has even taken place in ulcers which were rebellious to treatment by iodioform.—Moniteur de la Policlinique, November 4, 1883.

THE PROPOSED NEW MEDICAL LAW.—A correspondent from the interior of the State sends us a criticism of the proposed new medical law and suggests a substitute. He says: "The question is, Will the bill sent out by the Erie County Society, bring about the desired result? In my humble opinion, the most decided, no! Why? I see the amount of money that will arise from the assessment upon the whole number of candidates for a license! forty dollars per poll! making a grand total of nearly or quite forty thousand dollars. This amount to be divided among nine men, who would probably devote about ten or twelve days to the work of examining such candidates; a lucrative office for the length of time necessarily occupied in examining the afore-mentioned candidates."

Our correspondent's criticism is founded upon a misapprehension. There are not one thousand new doctors annually in the State; the number is more nearly one hundred. He suggests, in place of the present law, one which will compel the colleges to give a four years graded course. This means that the State practically take charge of the colleges. We have not arrived at the stage when that can be done, even if it were desirable. The proposed law makes provisions for having only wellqualified and educated medical men admitted to practice in the State. Justice and public health demand this, and we cannot ask much more.

THE ACTION OF NAPELLINE IN A CASE OF FACIAL NEURALGIA.—Dr. Grognot, of Milly, relates the history of a patient, a young unmarried woman, who was in perfect health except for a severe form of neuralgia affecting the first and second branches of the trigeminus. The pain was worse at about the menstrual period, although this function was performed normally. The pain was worse on the right side, and there were painful points. She had taken various drugs, including "acotine cistillisée," but without relief. Grognot prescribed napelline in pills and 20 gr. of a solution in 24 hours. The relief was very rapid and permanent.—Bulletin General de Thérapeutique, September 15, 1883, p. 221.

dread especially asphalt; then cement, next comes stone flagging, and finally bricks, which they prefer to any of the others. It does not seem to be a simple question of standing upon a cold floor, since the brick pavements are as cold as the cement or the asphalt. If there be really any relation here of cause and effect the evident lesson would be that wooden floors should always be preferred to the more modern style of pavement.—Lyon Medical, October 28, 1883.

CALCIFICATION OF THE PLEURA.—Dr. A. Gilbert relates the case of a man, sixty-six years of age, who died from gastro-hepatic carcinoma and pulmonary phthisis. At the autopsy, in addition to the visceral and pulmonary lesions, there was a calculus of calcareous matter in the right costal pleura. The membrane was involved to a considerable extent, forming a patch about eight inches in length by five inches in width. The outer surface of the patch was separated from the ribs by a dense layer of connective tissue. Its inner surface was very irregular, seamed with cracks, studded with little conoidal knobs, and closely attached to the pulmonary pleura by a number of old fibrous adhesions. It gradually increased in thickness from before backward, being at the sternum scarcely one-fifth of an inch in thickness, but more than three-fifths at the spine. There were two layers, the central one whitish, resembling bone, the cortical one yellowish, looking like horn. This latter was found to be an extremely dense connective tissue containing much connective tissue and calcareous matter. But though to the naked eye it resembled bone, the histological examination showed the absence of anything resembling osseous structure.—Le Progrès Medical, October 27, 1883.

THE ETIOLOGY OF INFLAMMATION OF THE JOINTS.—Professor M. Schiller asserts that the former views of the origin of joint inflammation from external causes are erroneous. There can be no inflammation without the presence of the excitation of inflammation. The latter may be inorganic (chemical), or organic (micro-organisms). These excitants may reach the joint in either of three ways: directly through an open wound, from the blood, or from the periarticular tissues. It was formerly thought that every joint-wound must of necessity cause inflammation and suppuration, but now experience teaches the contrary when antiseptic measures are employed. The belief that traumatism, without opening of the joint, is of itself alone a cause of arthritis, the author regards as likewise erroneous. He confused the joints of healthy animals without seeing any inflammation follow. After such injuries he found effusions of blood, and sometimes very small collections of round cells in the subsynovial fatty tissue, but nothing else. When, however, any infectious matters were injected into the body at a distance from the joints, there was almost invariably an inflammation of the joint, originating from the point at which the sanguineous exudation took place. The infecting material found entrance into the joint from the blood. In an analogous way arise inflammations of the joints without the intervention of traumatism, as in gonorrhea, rheumatism, metastatic arthritis, etc., where the poison exists previously in the blood. The poison is usually organic in its nature, but may be purely chemical, as in gout. The third mode of origin, where the poison is transmitted directly from the infected to the synovial membrane, is met with in the infective joint diseases, after acute osteomyelitis, erysipelas, etc. The joint infection may occur here in either of three ways: by the direct emptying of a neighboring collection of morbid material into the joint, as may happen in syphilis, tuberculosis, or infectious osteomyelitis; by a gradual extension of the disease from the surrounding tissue; and, thirdly, by the rapid transplantation of morbid materials through the lymph channels.—Schmidt's Jahrbücher, October 17, 1883.
THE MEDICAL RECORD:

THE SIMS' MEMORIAL FUND.

In another column will be found an appeal to the medical profession of the world for a memorial tribute to the late Dr. J. Marion Sims.

We doubt not that the sentiments which actuate the movement will be warmly appreciated by his many friends and admirers. Few men were privileged to do, even during a busy lifetime, as much for alleviating the sufferings of womankind as Sims.

Endowed with an original mind, with a genius for invention, with a rare skill in operative procedure, he justly earned for himself the proud name of the Father of Scientific American Gynecology. Almost every advance made in his chosen field of research bears the impress of his master-mind. From the time he first demonstrated the possibility of curing vesico-vaginal fistula by his original method, his irrepressible fertility of resource marched steadily from conquering unto conquests, until his fame as an investigator, and his skill as an operator, were spread throughout civilized Christendom. But his good deeds, his work so well done, his grand reputation so honestly earned, are now matters of history.

To perpetuate his memory in some more substantial way than by mere eulogy, is a privilege which will doubtless be becomingly appreciated by all who have been benefited directly or indirectly by his teachings and practice. The way is now open for the response. Any one inclined to do so is invited to contribute, and due acknowledgment of the amounts subscribed, and the name of the subscriber will be regularly credited in our columns from week to week, beginning with our next issue.

We also propose to publish, in the first number of each month, the full list of subscribers and their subscriptions, duly supervised by the Central Committee.

As stated in the circular of the committee, all contributions should be addressed to

THE MEDICAL RECORD,
NEW YORK,
N. Y.

Checks should be drawn to the order of THE MEDICAL RECORD, which will cheerfully take upon itself the responsibilities of treasurer of the fund. The members of the General Committee will be increased from time to time, and such as have already consented to act in their respective districts are cordially invited to do so in such way as may best secure the end in view. In this manner it is to be hoped that the work may be properly systematized, and that the best directed efforts of the friends of Dr. Sims will find a hopeful realization.

The various medical societies throughout the world, to many of which the beloved Sims was either an active or honorary member, will also gladly aid the movement, which we believe is now auspiciously commenced under the guidance of the Committee.

Aside from honoring a medical brother, the profession can understand that by raising a monument to Sims, or contributing to an otherwise suitable memorial to him, they help to establish the principle that great deeds in medicine merit public recognition alongside of those in literature, art, and war. That to save human life, to devise new methods of alleviating suffering, to faithfully minister to the demands of a common humanity, involve wider aims and loftier purposes than those which thrill the poet, inspire the musician, encourage the artist, or stimulate the soldier.

SIR ANDREW CLARK ON CATHETER FEVER.

The discussion aroused in London medical circles a few weeks ago by Sir Andrew Clark’s remarks on catheter fever, has led to a renewed study of the subject. At a meeting of the London Medical Society recently, Dr. Clark presented his views again in a more elaborate form, and claimed that he had discovered or formulated a new group of symptoms which deserved the attention of the profession. Whether his claim is just or not, it certainly aroused an active and profitable discussion, in which gentlemen of such experience as Sir Henry Thompson, Mr. Savory, Mr. Reginald Harrison, and others, took part. We think that our readers will be interested in hearing again, therefore, about this hypothetical new disease.

It is very well known that there sometimes occurs after passing a catheter a number of morbid symptoms. There may be simply a “physiological rigor,” i.e., a chill without fever; or there may be a “pathological rigor,” i.e., a chill with fever, a condition which Sir Henry Thompson calls an “acute transient attack of urethral fever.” Then again, there may occur a number of febrile attacks, perhaps four or five, the patient finally recovering.

Fourthly and finally, there may occur a set of symptoms of a more serious character, which has been designated as “continuous urinary or urethral fever.” Here the patients are generally older, and have had some urinary obstruction for a considerable time. The bladder is usually hypertrophied, and there is probably some chronic interstitial nephritis. The fever is of a “low” type, with considerable constitutional disturbance, but no marked rise in temperature. The patient not infrequently dies.

Now, to the above varieties of post-catheterization disturbances, Dr. Clark proposes to add a fifth. We prefer to present the description of it in his own words, where he sums up his views:

“First, about middle life in men perfectly healthy, or with no discoverable evidence of disease, except, perhaps, and even then not always, a low density of urine, the commencement of the habitual use of the catheter is
sometimes followed by fever of the remittent type, which often ends in death; and, for the fatal issue in such cases, no adequate structural explanation can be found.

"Secondly, it is important that such a fever, arising in the midst of apparent health from such a seemingly small cause, and leading so often (as it certainly does) to a fatal issue, should be well and widely known, lest death should take the friends of the patient by surprise, and arrangements necessary to the welfare of a family should be left unmade.

"Thirdly, although it is well known that in persons affected with renal disease, or in chronic gout, or with grave disorders of the general health, the commencement of habitual catheterism is attended with peril to life from secondary fever, the fact that this fever may arise in what seems to be good health, and, without the mediation of any visible structural lesion, issue in death, is not well known, or at least well known only to a few, and has, I repeat, no adequate place in English surgical literature, or in the English surgical teaching of this time. Of course this knowledge will be found, as I have in a very imperfect way shown you, in special monographs and papers; but those are the luxuries of the few, and, for the most part, the luxuries of specialists who work in that direction; but such knowledge should be, as I think, fully imported into all common text-books, and so made accessible to the whole body of the profession.

"Fourthly, this fever is neither distinctly uremic nor distinctly pyemic; although having some of the characters of each, it has all the necessary characters of neither. Probably it begins in the nervous system. Probably the disturbance of the nervous system reacts, in the first instance, upon the general metabolism of the body, and, in the second instance, upon the secretory organs, beginning with the kidney. The effect upon the kidney may consist either in structural alterations of the kidney, invisible by the aid of our finest instruments of research, or, as seems to me much more probable, in alteration of the constitution of the blood, the dynamic condition of its constituents in the renal vessels essential to the elaborative action of the secretory cells thereof; and, lastly, the concurrence of these conditions may, and often is, enforced by septic re-absorption into the blood.

"Fifthly, a more complete knowledge of this variety of fever and of the conditions of its origin, maintenance, and increase, may, at least we may hope, lead to a material diminution of its mortality; and, even now, by treating in a serious manner entrance upon catheter-life, by taking the precautions set forth by Sir Henry Thompson, by great temperance in the use of foods and stimulants, by rest, warmth, and by other general means upon which I shall not dwell, such mortality, I repeat, may be possibly considerably diminished."

The general opinion, as expressed by Dr. Clark's critics, and the one which any careful observer would adopt, is that the existence of this new form of catheter fever, coming on in previously healthy men, is "not proven." The cases related are confessedly few, and post-mortem was obtained in only one instance.

We are taught, however, that caution is necessary in initiating patients with urethral obstruction into the catheter-life, even though they have been, and apparently still are, in good general health.

MEDICAL PRACTICE IN NEW YORK.

A disappointed physician of this city, who calls himself an ex-specialist, has been discoursing to a writer on the Tribune staff, and has taken the trouble to malign his profession in that paper to the best of his ability. He begins by saying that the condition of medical practice in New York "has been greatly injured by concessions about medical etiquette that involve a sacrifice of principle and seem to show that the money of the patient is the chief object in practice." "Systems of medicine different in root and branch cannot," says this astute individual "be brought together, except on the ground that one or both are humbugs."

Now the true state of the case is that nowhere is there less, comparatively speaking, of the humbug known as homoeopathy than in New York City. Indeed New York is the only large city in the country which has no professedly homoeopathic medical journal, while the leading medical society of quondam homoeopaths has renounced entirely Hahnemannism and dogmatic medicine.

We will not open up the subject of the "concessions about medical etiquette," but will simply say that these so-called "concessions" have been in the interest of a higher morality, and have had for their object the inculcation of greater individual honesty. We trust and believe that the physicians of New York City feel more earnestly than ever the obligations imposed upon them as educated and responsible gentlemen. If there occurs a moral decline, it will be because certain medical cliques unite to fill the city with imperfectly educated doctors who find that they must live.

Our misanthropic ex-specialist continues as follows: "Again, the tendency in New York is for everybody to set up as a specialist. One man takes hold of skin diseases, another of nose diseases, a third of the ears, a fourth of the spine, and they call themselves specialists in many cases when they are nothing of the kind, and are not as well posted as an ordinary country family doctor who attends to everything. The object of the specialty distinction is to charge excessive figures to unwarnty patients. You understand it," continued the doctor, "when you know that if anything happens to you out of the common your friends are immediately telling you to go to this or that specialist. If you have a little twinge of the gout, yonder is somebody who makes it a grave matter that he attends only to rheumatism and gout. In short," said the doctor, "there are too many men in the profession, and too many of those are looking for something to raise the wind. Indeed, I regard this specialty dodge as sometimes hardly up to the level of patent medicine dignity."

We have often taken the opportunity to criticise the evils of specialism, and we are not prepared to deny that there is a tendency for too many to take up some particular branch of medicine, though no more in New York than in some other cities. But we have never heard that this tendency extended to "everybody in New York." On the contrary, the gentlemen who are at all known in this city as "specialists" do not amount to five per cent. of the total number. Our very fine-spirited ex-specialist forgets that a doctor has to work many years before he can succeed as a specialist; that, taking it all together, it is the general practitioner
who makes the most money; and that the young man who
takes up some specialty and thinks he can at once
charge high fees for his services soon finds his mistake.
In fine the "specialty dodge," as our highly ethical ex-
specialist insultingly terms it, is not a money-making
dodge at all—unless the individual becomes an out-and-
out quack.

It is unfortunate that gentlemen who find that things
do not go in the medical world just as they wish should
at once conclude that we are all going to the bad. But
it is worse than unfortunate, it is unpardonable and in-
decent that such persons should resort to the daily pa-
ers in order to proclaim their grievances and defame
their profession.

The National Code of Medical Ethics forbids this.

THE EDUCATION OF THE LAITY.

We publish elsewhere a communication on the subject
of the education of the laity in matters relating to medi-
cine and medical men. Our correspondent feels that
the extreme activity with which quack remedies are
thrust upon the people is creating a hurtful impression
as to the true value of the medical art, and that people
are encouraged to look more and more with favor upon
the pretensions of secret specifics and confident charla-
tans. The fact that the annual consumption of patent
medicines is so enormous, and that so many religious
journals stand upon a firm financial basis, gives much
support to our correspondent's assertion. We are cer-
tainly quack-ridden, and perhaps the rising generation
is becoming quack-educated.

Some remedies are suggested. The plan of having
medical societies arrange for the delivery of popular
educational lectures seems to have worked well in cer-
tain sections. In other places it would not be practica-
ble. American adults dislike the didactic, and the last
thing about which the average healthy man wants to
know is his body and how to take care of it. There
are some simple and fundamental facts, however, which
could with profit be impressed upon young people who
are still in school. For example, many even intelligent
persons are not aware that reputable physicians do not
advertise themselves or their special merits, do not
promise a cure for so much pay, and do not believe that
any single method of treatment relieves all diseases.
The young might well be taught also that there are cer-
tain diseases for which there are no infallible cures, that
there are others of which cure or relief occurs only
under certain conditions, and that the advertisements of
specifics should always be regarded with the utmost sus-
picion. There are thus many things which it would be
of service for people to know in the practical relations
of life, and which should properly form part of the educa-
tion of the young.

But, besides such education of the laity in the schools
and by suitable lectures (in which latter there is an el-
ment of danger), our correspondent suggests the use of the
pen and the press. He has already put in practice a
scheme which he describes and which has already been
commented upon favorably. It consists in distributing
sheets of paper to be used as wrappers, which are printed
on both sides with selections from the Code on the "Du-
ties of Patients to their Physicians," interspersed with
anecdotal paragraphs. While some good can come, no
doubt, from the diffusion of ethical instruction in this
way, human nature is obdurate, and the didactic wrap-
ners carry, perhaps, too little authority to initiate any
great moral changes.

It has been further suggested that some authoritative
and energetic association of medical men be formed who
shall push this matter of the instruction of the laity into
the wiles of quackery and the truths of rational med-
cine. Some counter-advertisements in the pages of the
religious journals might even be attempted.

A MEDICAL COLLEGE CRITICISED.

A correspondent of La France Médicale, who states
that he lived four years in Richmond, Va., and pre-
sumably graduated in medicine there, describes the status
of medical education in that city. Richmond, he says,
possesses a medical college and two hospitals. The
medical students, however, do not go into the hospital
wards at all, a sort of clinic being arranged for them
from the dispensary and walking patients. "After two
years, no more, of questionable study, the young men
leave furnished with doctors' diplomas." The writer
states that the education thus received is so imperfect
that the establishment of post-graduate colleges is a
legitimate outcome of the demand by conscientious
practitioners for more thorough clinical instruction.

The main charges made against the Richmond colleges
are those of slovenly teaching, short course, and incom-
plete clinical instruction.

The Southern Clinic asserts that the condition of affair
thus described is true. We do not imagine that the
Richmond Medical College is worse than a good many
other second-rate provincial schools. No doubt the
faculty do their best with the competition for students at
Washington, Baltimore, and the State University.

None the less it is not agreeable to have the faults of
our educational methods heralded in leading foreign
journals. It is the penalty which the profession must
pay for its long indifference to the impositions put upon
it by the speculative financial bodies known as medical
colleges.

SOME BAD MEDICAL LAWS.

A cry comes from our brilliant contemporary The Medi-
cal Age, that the medical registration law enacted a year
ago by the legislature of Michigan, is worse than a failure.
The law in question appears, from the Age's description,
to be a glittering illustration of legislative incapacity, and
has so far only worked mischief to the profession. In
the first place, it allowed every one who had practised
in the State as a physician or surgeon for five years to
register and obtain a license to pursue his work. In
this way a legal status was given to quacks, mounte-
banks, Indian doctors, medical students, etc. Further-
more, the law makes no provision for registration after
September, 1883.

Another State in which complaints against the medical
law are made is California. Here we have an interest-
ing example of catholicity as regards medical sects. The
legislature has established three Boards of Examiners—
Regular, Homoeopathic, and Eclectic—each being empowered to grant licences. "Our medical law does not give entire satisfaction," writes the Secretary of the State Board of Health. "It is known that many have been licensed who are totally and notoriously unqualified to practise medicine."

Another State where complaints are made against the medical law is Mississippi. It establishes an examining board in each congressional district, and permits every one who practised medicine at the time of the passage of the law to register as a qualified practitioner for the small sum of ten cents.

In a number of the States the medical laws are bad because they are incomplete, these defects being chiefly of a negative character. In other States, and in those above referred to, the law is positively mischievous because it legalizes quackery and keeps it legalized.

Many of the defects in the medical laws are due to inexperience or actual stupidity; some seem to have been helped into existence by the quacks. But none of them show that good medical legislation cannot be made a means of purifying the profession and benefiting the public. Future legislators can learn from past experience that the main points to be looked out for are: Careful provision for licensing and registering, efficient means for carrying out the law, and sufficient penalty for its violation.

MEDICAL ATTENDANCE ON SERVANTS.

A CORRESPONDENT in a recent issue of the London Lancet inquires as to the propriety, or rather the right, of a medical man to decline attending the servant of an employer who does not himself consult him professionally. We are glad to note that our esteemed contemporary takes the eminently just and sensible ground that the physician has a perfect right to refuse his services where he deems it incompatible with a proper maintenance of his own dignity and independence; while, on the other hand, an employer has the same undeniable right to secure what physician he wishes, if the contract be agreeable to each.

A far more practical and important point in connection with this troublesome question seems to have escaped the notice of our transatlantic brethren, and that is, the amount of the fee. Is the physician justified in charging the servant the same fee he would the employer? Now, of course, we are not familiar with the social exigencies pertaining to a community embracing the large establishments of a landed aristocracy. The semi-feudal condition of the Southern States during that halcyon period broadly designated as "before the war," is probably as close an analogy to such a state of society as American history can furnish. But even this analogy between "Jeames" and "Uncle Remus" is, on the face of it, an imperfect one. The intense vocabulary of the modern renaissance has indeed yclept the worthy possessor of abnormally developed gastrocnenii "vassal" and "retainer;" but his sable prototype, the "chattel," combined the real and the romantic in a far more practical sense, for he even formed a very palpable and prominent part of the "worldly goods" with which his mistress was endowed with her wedding ring, which is plainly the ultima thule of aestheticism. Now, to continue, soberly (for we assuredly do not wish to seem to treat this mat-

1. To the patient: Life, health, and occupation are placed in more or less jeopardy because a short-sighted member of a liberal profession inordinately seeks the "whole hog or none." (Mem.: He gets none.)
2. To the employer: (a) A feeling that this particular personal exudation of the "milk of human kindness" has decidedly soured; (b) a firmly fixed idea that the medical profession in general, and his own medical adviser in particular, are extortionists of the deepest dye; (c) an emphatic determination never to call in again that particular physician, and none other of that ilk, save for the most urgent need; (d) an additional emphatic determination to have all his servants treated gratis at hospitals or dispensaries to save bother.
3. To the doctor: (a) Loss of prestige with an influential family; (b) gain of one $5 fee possibly; (c) loss of a certain number of $2 fees; (d) a decided conviction that his vaunting ambition has in this particular instance palpably overreached itself.

4. To the profession: (a) A disastrous false impression unnecessarily created in the minds of the laity; (b) actual loss of every small fee otherwise obtainable from the employer.

5. To the community: (a) An uncalled for increase in the number of pauper patients to be supported.

Comment is unnecessary. It is often well to strike a balance sheet, à la Robinson Crusoe, even if the result be more striking than satisfactory. In a way it focuses the situation to one’s mind’s eye. We feel convinced that the sober second thought of the profession and the good sense of its members will not fail to perceive that our dignity and self-respect lose not a jot by a manly consideration for the simple rights of others. We do not believe that the policy we have alluded to is widely, or by any means universally, adhered to. Still the temptation does exist, and we should be quick to spy out the fallacy it rests on, and avoid yielding to its influence. If any practitioner believes his “good name” will not permit him to treat a servant without the accessory of a fee which has some pretensions to “great riches,” let him hand over the case to a younger brother, who has less “good name,” but perchance more good sense. In this particular, at least, let us be intelligent enough not to “kill the goose which lays the golden egg.”

THE COLLEGE OF MIDWIFERY.

We ventured some time ago to speak favorably of “The College of Midwifery” established in this city. The institution appeared to be respectable, and the work it proposed was a useful one. We regret to state that this “college” has forfeited all claims to the respect and support of the medical profession. It has adopted the extraordinary policy of openly soliciting patients and pupils for its infirmary and lecture-room, offering a per cent. of the receipts to the doctor or layman who sends in the material. We doubt if proposals so impudent and preposterous were ever distributed among the profession of the city before. As a matter of curiosity we present a specimen of the confidential offer made.

CONFIDENTIAL.

For Letter of Advice and Recommendation, we would be pleased to have you accept the following fees:

<table>
<thead>
<tr>
<th>Service</th>
<th>Fee</th>
</tr>
</thead>
<tbody>
<tr>
<td>Student to College</td>
<td>$10.00</td>
</tr>
<tr>
<td>Patient to Infirmary</td>
<td>25 per cent. on all Operations.</td>
</tr>
<tr>
<td>Patient to Maternity</td>
<td>$10.00 to $25.00</td>
</tr>
<tr>
<td>Confessions attended in Person, entire Fee.</td>
<td></td>
</tr>
</tbody>
</table>

The extraordinary action of the College of Midwifery, in issuing notices such as these, is the more to be deplored since it has tended to do an injury to its Censors, Drs. Mundò and Dawson. We have received a letter from these gentlemen in which they state that the course taken by the “college” was entirely without their knowledge and approval.

It is unnecessary for us to say more. The College of Midwifery, of New York has collapsed, morally, and will no longer receive the countenance in any way of reputable medical men.

---

THE ERIE COUNTY MEDICAL SOCIETY held its annual meeting on January 8th. The Committee on Legislation made a report concerning the efforts made to have a bill passed by the Legislature for the establishment of a State Board of Examiners. The committee stated that from every county in the State words of commendation for the project have been received. In several counties action has been taken by societies indorsing the bill. The Erie County society was congratulated upon the fact that this matter is now before the entire medical profession of the State, and there is concerted action in behalf of the object. A resolution was adopted urging the Senators and Assemblymen from its district to interest themselves in behalf of the bill.

TWENTY-SIX TRAINED NURSES were graduated from the Bellevue Hospital Training School on January 8th. Dr. T. Gaillard Thomas delivered an admirable and practical address to the young women. He charged them to avoid a few shortcomings with which the professional nurse is sometimes unjustly charged: Causing unnecessary annoyance and trouble to the family, carelessness in wearing clothing which cannot be washed, and which disseminates germs of disease, ignoring country physicians, getting into relations of maudlin sentimentality with patients, despising menial duties in the sick-room, and not carefully guarding family secrets. Each graduate was presented with a gold badge, the emblem of piety, watchfulness, and beneficence.

CHOLERA.—A letter from the State Department, received by the Secretary from Mr. E. E. Farman, an American judge of the International Tribunal of Egypt, gives the following: “There is a continuation of the cholera in Alexandria. There are from one to three cases a day resulting in death, and many more in which the attacked recover. According to the previous history of the disease in Egypt it will probably continue all winter, and perhaps much longer. After the cholera epidemic of 1865 there were isolated cases for two years. The general state of health, aside from cholera, has been bad at Alexandria. Fever in various forms has been, and still is, quite prevalent. The number of deaths from cholera in all Egypt during the summer has, from all the information I can get, been double that given in the official reports.”

At Calcutta the cholera is decreasing. The United States Consul gives the total number of deaths from cholera at that place for the two weeks ending November 20th at forty-four.

YELLOW FEVER is reported by Assistant-Surgeon Main, U.S.M.H.S., as still prevailing at Manzanillo, Acapulco, and along the coast from the latter place to Panama, but that it is of mild form, though at one time the mortality at the first-mentioned place was ninety-two per cent., and the Captain of the Port, who is also a Justice of the Peace, was removed for not enforcing the quarantine regulations with more vigor.

The United States Consul at Guaymas reports, under date of December 12, 1883, that the so-called yellow fever has almost disappeared from the State; no cases
THE MEDICAL RECORD.

January 12, 1884.

now in this port, and the port authorities grant clean bills of health to vessels departing. In the capital of the State, Hermosillo, a few cases of a mild type are said to exist. During the past month but fourteen deaths from all diseases occurred in this port, seven of which are said to have been from the so-called yellow fever, among whom were M. F. Chapin, of Maine; O. N. Funk, of Michigan, and an Englishman, named F. Jolly. It is to be hoped that this fatal fever will never return to this coast; its ravages during the months of August, September, and October will long be remembered by the people of Sonora.

Yellow fever has again made its appearance at Rio de Janeiro after a lapse of twenty-four days, and the United States Consul states that the weather is very hot and dry. The reappearance of yellow fever at Buenos Ayres is also reported by the United States Consul at that place.

The total number of deaths from yellow fever at Havana for the three weeks ending December 29th was twenty-seven.

A circular has been issued by Secretary of the Treasury Folger to the collectors and other officers of customs, informing them that, by recent regulation of the Peruvian authorities, all vessels arriving in a Peruvian port are required to be provided with a Bill of Health certified to by the Peruvian consul at the port of departure, in default of which they will be subjected to quarantine and fine.

INTERNATIONAL CONGRESS OF HYGIENE.—An official communication from the Secretary of State gives the information that "according to a note from the Minister of the Netherlands, here, the International Congress of Hygiene will hold its next session at the Hague, on August 21st next, and that governments, states, corporations, etc., are invited to send delegates."

EPIDEMIC OF MEASLES IN BALTIMORE AND WASHINGTON.—Surgeon-General Hamilton, U.S.M.H.S., received official notification of an epidemic of measles as now existing in Baltimore. Over five thousand cases of this disease occurred in Washington, D. C., up to December 31st, so says the Health Officer.

NEW YORK PATHOLOGICAL SOCIETY.—At the anniversary meeting, held January 9th, the following officers were elected for the ensuing year: President—Dr. George F. Sh pry; Vice-President—Dr. R. E. Van Gieson; Secretary—Dr. Wesley M. Carpenter; Treasurer—Dr. John H. Hinton; Editor—Dr. John C. Peters; Associate Editor—Dr. Frank Ferguson; Committee on Admissions and Ethics—Drs. F. R. S. Drake, J. C. Peters, J. H. Hinton, V. P. Gibney, and J. H. Ripley; Committee on Publication—Drs. Beverley Robinson and E. C. Wendt.

ANNOUNCEMENT CONCERNING THE WARREN PRIZE ESSAY ON CANCER.—Dr. J. Collins Warren announces that six essays were received on the subject of the "Probability of the Discovery of a Cure of Malignant Disease, etc.," and for which a prize of $1,000 was offered. None of these essays were deemed worthy of the prize.

A BILL TO REGULATE THE PRACTICE OF MEDICINE AND SURGERY, was introduced in the General Assembly of Virginia on Tuesday last.

THE HOSPITAL COLLECTIONS up to January 9th, amounted to $22,532.85. In 1883, the amount was $33,862.72; in 1881, $42,535.47; in 1880, $44,371.97; in 1879, $46,455.07.

NEW YORK ACADEMY OF MEDICINE: ELECTION OF OFFICERS.—At the annual meeting held January 3, 1884, Dr. Robert F. Weir received 101 votes for Vice-President, Dr. Henry D. Noyes, 42; Dr. C. R. Agnew, 101 votes for Trustee, Dr. S. S. Purple, 43; Dr. F. A. Castle, 101 votes for Treasurer of the Board of Trustees, Dr. J. H. Hinton, 44; Dr. Daniel Lewis, 100 votes for member of Committee on Admissions, Dr. E. H. Jones, 43; Dr. C. D. Varley, 106 votes for member of Committee on Ethics, Dr. F. V. White, 35; Dr. W. G. Wylie, 106 votes for member of Committee on Education, Dr. John Shrady, 38; Dr. A. Jacoby, 101 votes for member of Committee on Library, Dr. H. D. Nicoll, 44.

DR. GUSTAVE RIVET, interne de Charité, died recently of diphtheria contracted during his service in the hospital.

THE BRITISH OPHTHALMOLOGICAL SOCIETY has decided to found a museum and a library.

A GYNECOLOGICAL SOCIETY IN PARIS.—A new society, called the Gynecological and Obstetrical Society, has been organized in Paris.

THE TREATMENT OF RUPTURAL FEVER.—In the article on this subject, page 15, the forty-third line, first column, should read: "Dr. Garrigue has used carbolic acid regularly for eight years for hand instruments," etc. Last line should also read: "To the embarrased mind it is clear as day that Dr. Garrigue's remarkable success is due to non-interference," etc.

THE PRIZES AWARDED BY THE ACADEMIE DE MÉDECINE were distributed at its meeting December 18th. Nine prizes were awarded, the total amount of money bestowed being 18,500 francs, or about $3,700. The whole number of prizes offered was fourteen.

THE LATE DR. SIMS AND AN ALLEGED INSTANCE OF "TRANSFERRED IMPRESSION."—The Philadelphia Medical and Surgical Reporter quotes editorially the following story, which is interesting on many accounts: "The daily papers tell us that at three o'clock one morning Dr. Mackey (a prominent physician of Washington) rose suddenly from his bed and began pacing the floor, which disturbing his wife she asked what ailed him. He answered that he had such a horror and vivid dream that he could not rest after it. He had dreamed that his friend, Dr. J. Marion Sims, of New York, appeared to him, with a face like that of a corpse, and said to him: 'James the Fourth is dead.' Dr. Mackey said to his wife that the dream so depressed him that he would not go back to bed again, so he went down to his office and sat there at work until after daylight. Before breakfast a telegram was brought him announcing Dr. Sims' death at 3 a.m., exactly the hour when Dr. Mackey, rousing from his dream, had looked at his clock. Looking at it again he found that it had stopped at three o'clock. Dr. Sims was in the habit of calling himself James the Fourth, as he was the fourth of the same name in his family." The editor of the Reporter accepts the above as true. This may be so, but even if so, one must re-
member the very great possibility of a coincidence. Millions of people dream that some friend is dead. In a few cases they seem to hit it. Besides, in the present case, Dr. Sims did not die at 3 o'clock A.M. but at 3.15.

VIRCHOW ON THE TUBERCLE BACILLUS.—At a recent meeting of the Berlin Medical Society, Professor Virchow made some observations upon the subject of tubercle, and the tubercle bacillus, which are of considerable interest. The occasion was the reading of a paper by Falk, in which that observer reported the results of some experiments made by him, in order to test the power of the bacteria of putrefaction to neutralize the special activity of the tubercle bacilli. His experiments had been negative. Virchow in his remarks did not commit himself fully to the theory of the bacillary origin of phthisis. He called attention to the distinction which must be made between a contagion and an infection. In an infectious disease, like malaria, the whole of the bodily tissues are affected—there is, in fact, a dyscrasia produced. In a contagious disease the poison acts upon certain parts of the body, and from these foci the injurious influences are disseminated and affect the system. In this latter class of diseases one must place those in which the morbid processes are produced directly by the micro-organisms, and we could not expect that here one attack would secure indemnity against another. Virchow referred to the recent experiments of Roloff, which confirmed those earlier made by himself, to the effect that anthrax could be produced by inoculating animals with blood free from organisms. He admitted that Pasteur's preventive inoculations were a success from a scientific point of view, but failed, as yet, to act well practically. He referred to a dialectic difficulty caused by the wrong use of the word "tubercle," and thought that cheesy pneumonia and phthisis, if really caused by a specific bacillus, ought to be called bacillary diseases, rather than tubercular, since the latter name is more anatomical and clinical.

ANTI-VIVISECTION IN GERMANY.—The anti-vivisectionists in Germany have succeeded, in opposition to the Cultus-minister von Gossler, in getting a petition through the Chamber of Deputies requesting the Government to consider how far vivisection could be dispensed with as a means of teaching and investigation. The decision of the Government has been received, to the effect that the matter is still under consideration, and that it is intended during the present winter session to demand an opinion from the whole of the medical faculties, and that a memorial on the subject was in course of preparation.

BERLIN UNIVERSITY.—The number of students for the winter semester is 4,635. The number of medical students is 878, among whom are 80 Americans.

Dr. A. F. Holt, of Cambridge, has been appointed Surgeon-General of Massachusetts.

A GOVERNMENT QUARANTINE STATION for imported cattle has been permanently established at Garfield, N. J.

Dr. E. DARWIN HUDSON, JR., has been appointed visiting physician to Bellevue Hospital, vice Dr. Henry F. Walker, resigned.

THE LONDON INTERNATIONAL HEALTH EXHIBITION.—The proposed Health Exhibition to be held in London next summer is destined to be a success. The Queen has become its patron, the Prince of Wales chairman of the Executive Committee, and prominent members of the nobility have interested themselves in it. The Corporation of London has already voted $25,000 to help it along. Punch states that there are to be effigies in wax of the writers on Tbe Lancet among the objects of interest in the exhibition.

THE SIMS MEMORIAL FUND.

To the Medical Profession and Others throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting testimonial than obituaries and eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations; and such as have had the direct advantage of his personal skill are among the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulse to the study of gynecological surgery in America.

It is believed that the medical profession everywhere, the vast number of women who owe their relief from suffering directly to him, and those who realize the benefits he first made possible, will gladly unite thus to honor the man through whose original and inventive genius such blessings have been conferred upon humanity.

At the suggestion of many friends, therefore, the subjoined committee has been organized, and it is proposed that a suitable monument be erected to his memory in the city of New York.

To this end the active co-operation of the medical profession and the many other friends of Dr. Sims throughout the world is respectfully solicited. Contributions of one dollar and upward may be forwarded to the journal which has been constituted the treasury of this fund—The Medical Record, New York.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Annual Meeting, January 3, 1884.

FORDYCE BARKER, M.D., L.L.D., PRESIDENT, IN THE CHAIR.

REPORTS OF COMMITTEES.

In the general report of the Council, it appeared, from the report of the Assistant Librarian, Mr. J. S. Brown, that there had been a marked increase in the number of readers during the last year, made up of physicians, lawyers, and laymen from all parts of the State.

The report of Dr. S. T. Hubbard, Treasurer of the Board of Trustees, showed a balance of the Academy fund of $295.27; of the library fund of $4,312.40; of the special library fund of $60; of the general permanent fund of $1,101.56; of the fund for the liquidation of the mortgage of $1,185.77.

The report of the Recording Secretary, Dr. W. H. Katzchenbach, showed that 20 candidates had been elected, of whom 17 had completed their membership; that death had removed 7 resident, 1 non-resident, and 1 honorary Fellow; and 1 had removed by resignation. The whole number of members is 383 resident, 18 non-resident, 4 corresponding, and 6 honorary Fellows.

The reports of the Foreign Corresponding and the Statistical Secretary were read by titles.

The report of the Committee on Admissions showed that 30 physicians had applied for membership, 23 of whom had been recommended, and 7 are yet before the Committee.

The report of the Committee on Library spoke of the steady growth and the prosperous condition of the library.

PRESENTATION OF A MEMORIAL PORTRAIT OF THE LATE JAMES RUSHMORE WOOD, M.D., L.L.D.

Dr. F. H. Bosworth said that in presenting this memorial portrait to the Academy as a gift from Dr. Wood's old students, he might speak of their preceptor as one of the great surgeons of this country, or as a clinical teacher; but it was not as a great surgeon nor as a clinical teacher that Dr. Wood endeared himself most unto them, but as an earnest, faithful, and soul-inspiring friend of the medical student. It was in this spirit that he asked the President to accept the memorial portrait of their old preceptor, painted for them by the accomplished artist, Mr. T. Hicks.

The President, in behalf of the Academy of Medicine, accepted this valuable addition to the portrait gallery, and requested Dr. Bosworth to express to those who together with himself had so nobly and wisely contributed for this purpose, the Academy's full appreciation of the gift, which as a work of art presented a striking degree of high merit, and would always be an ornament to the present or any future hall the Academy might possess. As a portrait, it is not a mere topographical outline of the lineaments of our friend and distinguished associate, but it faithfully expresses the force of character, and the power of mind, the calm and forceful mind, the power of mind and ambition of a reflecting and philosophical mind. As it hangs upon these walls it will always be a great moral lesson to the young men who come hither, as to the nursery of future professional growth, and an illustration of how ability, honest work, indefatigable industry and perseverance will secure eminence and distinction, and these without the aid of those favoring elements, wealth and family influence, and helpful pushing of enthusiastic friends.

Dr. Frederic S. Dennis then delivered a memorial address, in which he reviewed the life of the distinguished surgeon, who was born in 1813, and received the degree of doctor in medicine at Castleton, Vt., in 1837. It was an interesting and faithful picture of the life-work of Dr. Wood in private and hospital practice, his labors in behalf of hospitals and training-schools, and for the welfare of the general profession. A touching reference was made to the last time his voice was heard in public debate, when in the hall of the Academy he met the views set forth by his distinguished friend and colleague, Dr. J. Marion Sims, concerning the treatment of gunshot wounds of the abdomen, whose memoir was soon to be read by Dr. Emmet.

At the close of the memoir, Dr. Murphy, of Mount Vernon, N. Y., one of the two only surviving fellow-students of Dr. Wood, was introduced to the Academy.

Dr. Hunt, Surgeon to the Pennsylvania Hospital, was also introduced to the Academy.

Dr. Thomas Addis Emmet then read a MEMORIAL OF THE LATE J. MARION SIMS, M.D., L.L.D., who was born in 1815, and graduated in medicine at Jefferson Medical College in 1835. Dr. Sims was by nature a surgeon, and one of the most dexterous operators he ever witnessed. He was bold and self-reliant, never at a loss, and his ingenuity was unqualified. He was in no sense a plodder, for his mind and body were always too restless and active. He was so fertile in resource when I first knew him that he perfected scarcely a tithe of the brilliant conceptions passing currently through his mind, and it is impossible for him to perform the most simple operation without learning something new." Such was the estimate of his memorialist, than whom no one is better qualified to speak.

Dr. Emmet then gave a brief synopsis of the work done by this eminent surgeon and "the father of American gynecology." Brief reference was made to "who continued as the support and stay of many, and helpmate through a long life, who devoted her life to his husband, and upon whom no person was ever more dependent upon another than he was upon her."

"My relations," said Dr. Emmet, in closing, "with Dr. Sims in early professional life were as close as that could be. Later on, from circumstances which I need not state, for which I had no control, we did not meet for years. During the summer of 1832, and in London, while I was closely watching the steps of an operation, some one came into the room breathing quickly, as if he had been ascending the stairs. For a second of time I was annoyed, as this gentleman sidled up so close to me, but his hand passed into mine as we passed, with a familiar voice, 'How do you, old Emmet?' and I shook Dr. Sims by the hand for the last time."

Speaking of the Woman's Hospital, Dr. Emmet said all credit must be given to Dr. Sims for the conception of this institution as well as the power of convincing others of the necessity for such a hospital, and his name must be forever identified with it as the originator. But his conception could never have reached a realization without the aid of others, for he had none of the qualifications of an organizer. Every one, with a single exception, connected with the project had received credit from some source, but speaking of the things of which he knew Dr. Emmet said that to Dr. Fordyce Barker more than to any other individual, we owe the early organization of the Woman's Hospital, and Mrs. Barker served two years as Secretary of the first Board of Managers of the Woman's Hospital Association.

SECTION IN OBSTETRICS AND DISEASES OF WOMEN.

Stated Meeting, December 27, 1883.

ALEXANDER S. HUNTER, M.D., CHAIRMAN.

DR. HUNTER was re-elected Chairman, and Dr. Henry Griswold was re-elected Secretary.

DR. E. L. PARTRIDGE read a paper entitled PERIHELIAL FEVER—AN OUTLINE OF ITS NATURE, MANIFESTATIONS, AND MANAGEMENT.

For convenience, Dr. Partridge adopted Spiegelberg's classification, chosen by Lusk, in his chapters on the sub-
ject of puerperal fever. A practical study of the clinical history and pathology of the affection seen in the puerperal patient leads to the conviction that there is, in the vast majority of cases, an upper genital tract infection in their causation. In a small proportion of cases the fever depends at the outset upon one or more local conditions, septic poisoning occurring at a later period in the puerperal state. In a few rare cases we may believe that we have simply the manifestations of local affection from first to last. Some would question the truth of the last statement, but the author of the paper could not believe that the recently delivered woman might not suffer from cellulitis or peritonitis, as well as that those diseases might arise independent of childbirth or septic infection. In almost all instances, however, full facilities for clinical and pathological examination will reveal unmistakable indications of the absorption of septic poison from some portion of the genital tract.

Dr. Partridge then spoke of the facilities for the introduction and development of septic poison in the lying-in woman, such as from the placental site, lacerations, etc. Septic material may be brought in contact with the absorbing surfaces in two ways: (1) Autogenetically, that is, by decomposition of blood, fragments of secundines, inflamed tubes, etc.; (2) by contamination by air. The last is, from exposure to atmosphere containing emanations from patients suffering from septicaemia, erysipelas, scarlet fever, diphtheria, or from direct inoculation, etc.

With regard to the nature and mode of action of the septic poison, Dr. Partridge thought the view that the contagious principle consisted of microscopic organisms (microbes) needed a ready explanation of the numerous lesions of puerperal fever, the variation being due to the different degrees and extent to which the blood-vessels and lymphatics were permeated. Besides, he regarded it as reasonable that the quality and kind of this microscopic poison might vary, and therefore produce a variety of lesions.

The last part of the paper then reviewed briefly the clinical history of endocolitis and endometritis, in the simple form, and also that known as ulcerative, diphtheritic, or septic, which is far more serious.

Parametritis or pelvic cellulitis is the puerperal inflammation which occurs most frequently, and it may be either septic or non-septic in character. Perimetritis or pelvic peritonitis is the most serious complication. General peritonitis is a common puerperal affection, and there are two varieties: (1) That which is due to septicaemia; (2) that due to an extension of the pelvic variety. In the septic form, pain and tenderness are wholly secondary to the prostration due to the blood-poisoning. The most prominent symptom for diagnostic purposes is persistent abdominal distention with indications of septicaemia.

Septicaemia has a protean character, but the symptoms are clearly demonstrable after the second week, such as chills, profuse sweats, rise and fall of temperature (never reaching normal), irritable stomach, yellow skin, costal tongue (disposed to be dry), low delirium and hallucinations, septiceps shall also shake the mental faculties dull. There will also be present indications of one or more of the local septic inflammations.

With reference to prevention and treatment Dr. Partridge maintained that an uncontaminated atmosphere was the first essential. Inasmuch as the poison can be conveyed from place to place, the greatest care must be exercised by physicians, nurses, etc., that they carry the disease from one patient to another. In prolonged labors it is necessary, and it is proper in all cases, to use disinfectant vaginal injections during labor, and their judicial use, not too frequent, is called for after labor.

The proper management of the third stage of labor is important in checking the complete expulsion of clots and secundines and personal uterine contraction. The hands of the accoucheur should be scrupulously clean, especially the finger-nails, and rendered antiseptic.

In cases of septicemia, when the point of inoculation is within the uterine cavity, or where it is known that this cavity contains decomposing fluid, warm carbolized intrauterine injections should be employed, and they usually cause the temperature to fall promptly. Care is necessary that the injection be made slowly, and that there is free escape for the fluid. If sloughs occur they should be removed as early as possible, and contiguous exposed surfaces should be covered with iodiform, or touched with carbolic acid or tincture of iodine. In local or general perimetritis leeches only may be beneficial. When exudation is present vaginal injections of hot water and externally poultices may be serviceable. Pelvic abscesses should be treated by aspiration or incision. Opiates to relieve pain, quinine for its antipyretic and supporting effect, and stimulants as indicated. Food should be concentrated and easy of digestion. General blood-letting is improper at any stage of general septicemia. If arterial sedatives are used their effect must be watched with the greatest care. Salicylic acid may reduce temperature, and the wet pack, carefully employed, may be equally useful. Stimulating enemata, aassacetaed or turpentine, or even aspiration of the intestines with fine needles will afford some relief from excessive intoxication.

Dr. John C. Peters said that one readily gets the idea that there are two varieties of puerperal fever: first that which is of septic origin, and second the affection which does not depend upon sepsis. The remedies, also, can be divided into two classes, opium, calomel, carbolic acid, quinine, and camphor should not be used in the acute form of the disease, for micrococci will live in these drugs.

On the other hand, the mineral acids, such as sulphuric, nitric, muriatic, will destroy these organisms when used in very weak solutions. Twenty drops of a solution consisting of ten drops of the strong sulphuric acid to one ounce of water, will kill the bacteria in two ounces of fluid; as a five-grain tablet of the tartaric acid will kill bacteria quicker than will carbolic acid.

Dr. Peters spoke especially of the value of bichloride of mercury and turpentine as germicides, the former of which will kill the germs when used even of the strength of i to 20,000; of course a much stronger solution could be used with safety.

Dr. Pablo Mandé saw nothing in the paper to which he wished to take exception. He wished to say, however, that Dr. Partridge had omitted to mention one of the causes of puerperal fever. He had always believed, as had been advocated by Dr. Thomas in a recent paper, that in the majority of cases puerperal fever is puerperal septicemia due to absorption of poisonous matter from the genital tract. But Dr. Mundé did not make this the cause for all cases; that is, he could not help leaning somewhat toward the view that puerperal fever may be a disease by itself. He had seen cases in which there was no evidence of septic absorption. He would say, therefore, that while in most cases puerperal fever is puerperal septicemia due to absorption of septic material from the genital tract, in some cases puerperal fever is due to a cause, the exact nature of which is unknown.

With regard to intra-uterine injections, Dr. Mandé thought that neither the author of the paper nor Dr. Thomas had spoken sufficiently of the exact indications for their use. It will not answer to simply say that every rise in the temperature is a sign of uterine infection, that a fistula discharge from the vagina we must wash the uterus out. Not at all. There must be more exact indications. He then referred to a case under his care at the time Dr. Thomas read his paper, and in which there was a rise of temperature to 103° F. before listening to the paper, and to which, after the meeting, he returned with fear that the temperature was a four days' temperature of 104° F. There was no fistula lochia. It was at about the time for the beginning of the secretion of milk. He did not in-
ject the uterus, the temperature fell under the influence of aconeit and twenty grains of quinine, and the subsequent progress of the case was favorable.

Dr. Münde believed that the mere rise of temperature did not indicate the use of intra-uterine injections; nor did he believe in an association of the two, or a combination with other symptoms, as with a chill, or manifest constitutional disturbance, to call for their use in the puerperal state. The very absence of lochial discharge may be a good reason for washing out the uterus, fetid or otherwise. He then referred to a case in which the lochia was retained on account of a fistula of the uterus, absorption took place, and a chill occurred. He corrected the malposition, and a large quantity of fetid lochia was discharged. The mere absence of fetid lochia, therefore, would have been an unsafe guide in deciding whether or not the uterus should be injected. He did not wash out the uterus unless the condition of the lochia meant something more than mere offensive or fetid lochial discharge.

The very worst cases of puerperal fever are those in which there is entire absence of local symptoms, and the patient appears to be quite comfortable.

As to the manner of giving intra-uterine injections, Dr. Münde did not agree with Dr. Thomas at all. He had long ago abandoned the practice. Dr. Davis, of Cincinnati, and the hands of competent nurses, had produced the most severe collapse. He objected to propelling a stream of water with force into the puerperal uterus. He also believed there is a time when intra-uterine injections are no longer useful. When the temperature is not reduced permanently within forty-eight hours, the injections having been given three or four times a day, the measure will, as a rule, fail. It is true there are exceptions to this rule, as there is to all others. He was quite sure that he had several times seen a chill with rise of temperature follow an intra-uterine injection. When the discharge was no longer offensive and the uterus was widely dilated, he had seen patients who were suffering from the worst form of puerperal fever.

With reference to parametritis and perimetritis during the puerperal state, Dr. Münde had seen cases where the pulse and the temperature were those of septicemia, but an examination always revealed an exudation in the neighborhood of the uterus, and made the diagnosis clear. When there is such a local inflammation, do not wash out the uterus.

As to the drug to be used, he was inclined to favor the chlorohide of mercury, 1 to 2,000, for intra-uterine injections. His rule is, in every case of confinement, and especially if there is an outlook for a labor of unusually long duration, or it is likely to be difficult, or there is a probability that operative interference will be necessary, to wash out the vagina, perhaps after every vaginal examination, then immediately after the child is born, and also if he had introduced his hand into the uterus, to wash that cavity out with carbolised ice-water of the strength of two or three per cent. But why not hot water carbolized? He did not use hot water habitually because it could not be employed very hot without the liability of burning the patient, and even when warm it is not a hemostatic. Ice-water, however, is effectual as a hemostatic, and it will not injure the patient. Then administer a syringing of the fluid extract of ergot hypodermically deep into the abdominal walls, and also give ergot, quinine, and strychnia until the uterus is thoroughly invaginated into or three vaginal injections daily.

Dr. S. Baruch, of New York, told the audience that he had used ergot, and asked Dr. Münde if he used vaginal injections as a prophylactic measure after normal labor. Dr. Münde said yes; and he directed that they be given once, twice, or three times a day while he continued his visits.

Dr. Partridge also said that he had always used them for that purpose, but not oftener than twice a day.

Dr. Baruch thought it was inconsistent to regard the genital tract after normal labor as in a condition of traumatism, or like a wound after an operation, and then treat it altogether different. He believed it to be a practice fraught with some danger. At least, it had been found so in Germany. In America, he wished to record himself as opposed to these injections.

Dr. Daniel Brown also wished to put himself on record against the continuous washing out of the vaginal tract after normal labor. The genital tract of every woman after normal delivery is not necessarily in a septic condition, and besides he believed that considerable injury might be done by disturbing the patient, as must needs be for giving them. The genital tract is not an open one. If the canal is offensive, of course cleanse it with whatever remedies may be regarded as the best. With regard to quinine, he had never seen any benefit follow its use, in either large or small doses, for reducing septic fever.

Dr. Münde said that while it might not be absolutely necessary to give vaginal injections as a prophylactic after normal labor, yet he had not seen any damage done by ordinary vaginal injections with a fountain syringe; and thought it wise to resort to them.

With regard to the claim made by Dr. Brown that the ordinary lochia is not necessarily septic and that the lochia only begins to be a septic discharge, or in a condition favorable to the development of puerperal septicemia, Dr. Münde said Ahlfeldt had demonstrated that the most poisonous lochia was entirely inoffensive, and he further believed that no primipara is delivered without some lesion of the genital tract, and of multipara there is probably not a case in which there is not some laceration about the cervix. Besides, Ahlfeldt had shown that the most dangerous period in the puerperal state for septic infection is about the third day, and he therefore believed that vaginal injections should be given for four, five, or six days at least, when perhaps they might be safely omitted.

Dr. Brown said when he spoke of normal condition of the vagina, he did not mean absolutely, but that there is not sufficient injury to necessitate the disturbance of the patient for giving the injections. Of course, if any reason showed itself, as proved by the symptoms or the local conditions, he would use them without hesitation.

Dr. Baruch said he had learned that day of a case of puerperal fever, to which Dr. Münde was called in consultation. The patient had been delivered of a stillborn child, and had been given carbolised vaginal injections on the third day, and, on the fifth day after confinement puerperal fever developed, and probably the woman would have died had she not received the skillful attention of the consulting physician.

Dr. Münde said he did not recall the case.

Dr. Charles Jewett, of Brooklyn, had been accustomed to say that no physician can treat a score of fresh wounds with thorough antiseptic precautions without becoming a convert to antiseptic surgery. Theoretically, his convictions are equally strong as to the value of antiseptics in the treatment of obstetric wounds, which he believed always exist after labor. Practically, however, his experience is not fully in accord with his theoretical convictions as to the necessity for all the antiseptic precautions that have been recently advocated. A little more than six months ago he began a series of experiments in the maternity wards of the Long Island College Hospital to determine the value of certain antiseptic measures. These experiments thus far number about fifty, and the data is small but, it is true, to be of much value as evidence, but the results are at least suggestive. The first thirteen of these cases were conducted under the direction of a skilled obstetrician, with every safeguard except the use of special antiseptic measures. Thirty-six cases immediately following were conducted under the following precautions: The wards were alternately vacated and disinfected with chlorine.
on the 1st and 15th of each month. The beds were renewed throughout, even to the straw, on the discharge of the patient, so that each new patient went upon an entirely fresh bed. The bedsteads were cleansed antisepically. The usual antiseptic measures were enforced in case of the medical attendants and nurses. The vulva was regularly cleansed and constantly protected during the puerperal period with a guard of ointment dipped in carbolic or bichloride solution.

Of the thirteen cases, two (nearly sixty per cent.) had temperatures which at no time in the first week of the puerperium exceeded 99.4°F. Of the thirty-six cases, twenty-five (nearly seventy per cent.) at no time in the first week had temperatures above 99.4°F.

To test the value of the vaginal douche as a prophylactic measure, with a few exceptions every other case was doused twice daily or oftener during the lying-in period, beginning at the close of labor. Half the cases, therefore, were doused and half not doused. The fluid used was, in a portion of the cases, three per cent. carbolic solution; in the majority of them a 1 to 1,000 bichloride solution, both used warm. The temperature record thus far shows practically no evidence in favor of the douche. Involvement, however, appeared to be more rapid in the doused cases. True, this evidence is not conclusive, but it indicates the probable value in a given case gain access to the passages in spite of other precautions, then the douche might save the patient from child-bed fever.

For curative purposes the value of the douche is beyond question. He had resorted to intra-uterine injections only when vaginal irrigation failed to reduce the temperature. The few cases in which the intra-uterine douche he had not been wholly satisfied with the Chamberlain tube. He had had a smaller tube made, three-eighths inch in diameter with two holes only, on opposite sides and close to the end.

There are certain forms of child-bed fever, however, in which the antiseptic douche can have no curative value.

Dr. Partridge, in closing the discussion, said he certainly believed the vaginal douche is capable of doing a great deal of harm unless properly used. He would not trust to any nurse to give it, unless he knew positively that she was skilful. Then, if used twice in twenty-four hours, every seven days of normal labor, it can do no harm.

With regard to his suggestions for which the anatomical conformation of the parts is said to afford, he thought it a uniform experiment that when a digital examination is made the finger is covered with blood and mucus, offensive, and in a condition to readily become poisonous in character. He did not believe there is any single indication for the intra-uterine douche; it is only when there is a combination of symptoms which indicate the presence of decomposing substances in the uterus that it should be resorted to, and then not too frequently.

He favored the practice of supplementing it by the use of iodoform and glycerine—a ten per cent. solution—already mentioned in his remarks on Dr. Thomas' paper before the Academy.

With reference to puerperal fever depending upon some poison not septic in character, he must confess that he believed the question still to be an open one, although he was unable to see why those cases might not be of septic origin. They are cases of intense toxemia, although we do not know what the nature of the poison is, and he could not see why it might not be septic.

Dr. Partridge believed that labor is never completed without some laceration about the cervix.

The Section then adjourned.

A MAN WHO ABSTAINS FROM LIQUOR, as shown by insurance tables, at 20 years of age has a chance of living 44.2 years; at 30, 36.5 years; at 40, 28.8 years. An intemperate man's chance at 20 is 15.6 years; at 30, 13.87; at 40, 11.6.

Our London Letter.

(From our Special Correspondent.)

London, December 15, 1883.

Two more members of our profession have just been made baronets, viz., William Bowman and Joseph Lister. The former has long held the foremost place as an ophthalmic surgeon in London. His fame does not, however, rest on that alone, as many years ago he obtained a position as an original investigator in Physiology and Histology. It will doubtless be remembered by most of your readers that Mr. Bowman was the Honorary Treasurer of the Industrial Medical Congress held in London in August, 1881.

As the originator of the antiseptic system bearing his name Mr. Lister has gained a world-wide reputation, so that it is superfluous to speak of his merits here. Mr. Lister has also distinguished himself by various physiological researches upon the action of the antiseptic douches and the like.

So long as we have hereditary honors the above-named gentlemen cannot but be regarded as worthy recipients of them. Why should not peerages be awarded to medical and scientific men, though? The poet Ten-nyson has been elevated to the peerage. Why not Bowman, Jenner, Lister, and Paget? There could be at a rate not objection to making them living peers. Your readers will doubtless view the matter with different ideas, but if we are to have peerages at all surely such men as these are as worthy of them as Lords Wolseley and Alcester and life-destroyers like them.

The case of Messrs. Bower and Keates continues to attract attention. These gentlemen were prosecuted for malpraxis by the parents of a child suffering from diphtheria, for which tracheotomy was performed by them. On the part of the prosecution, I understand that an attempt was made to secure the adverse evidence of several well known specialists. I am glad to say these gentlemen declined to appear against their professional brethren. The case broke down, although the public prosecutor and counsel charged with the case were officially brought before both the College of Physicians and the College of Surgeons and on Monday evening last a meeting was held at the house of Sir William Jenner and a subscription list started toward defraying the legal expenses incurred in the defence.

The Bradshaw Lecture at the College of Surgeons was delivered on the 6th inst. by the President, Mr. Marshall. Several interesting facts were brought out by Mr. Marshall. He showed that nerves can be stretched, though they are not so extensible as one might imagine. Mr. Marshall showed experimentally that a nerve will not stretch very much more than a piece of tendon. After being stretched the recoil is considerable—to nearly its original length. Mr. Marshall showed that nerves will bear a very considerable traction without breaking. Stintzing observed that the healthy sciatic nerve would bear a strain equal to half the weight of the animal's body, i.e., one of seventy-five pounds for a man weighing one hundred and fifty pounds. But in dealing with diseased nerves it was unnecessary to apply so great a force, and thirty pounds was a reasonable force to apply. This was as hard as a man could well pull a nerve, holding it between his finger and thumb, so that practically there was little danger of rupturing the nerve. Less force must of course be applied to smaller nerves. Mr. Marshall believes the operation of nerve-stretching to be safe, and an efficient one for the cure of neuralgia.

Some interesting facts relative to myxedema were brought up at the recent discussion at the Clinical So-
ciety of London. Dr. Semon gave a résumé of Kocher's researches, from which it appeared that the extirpation of the thyroid gland has in some instances given rise to cretinism. If experience should show this to occur often it will add another to the dangers already attending the operation. It would seem, though, that where the extirpation of the gland is not total, but one lobe is left, that cretinism has not been observed to ensue.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE BANQUET TO PROFESSOR CHARCOT—THE ANALYSIS OF VARIOUS DIETETIC DRINKS AND ALIMENTARY SUBSTANCES—A NEW MEANS OF ADULTERATING MILK—HOW AMERICAN SWEETS ARE PAID FOR IN INTERESTING—THE AMERICAN PORK QUESTION—THE NUMERICAL STRENGTH OF THE MEDICAL PROFESSION IN FRANCE—THE INCREASE OF LUNACY IN FRANCE.

Paris, December 21, 1883.

Professor Charcot has been entertained at a banquet on the occasion of his election as member of the Academy of Sciences. The banquet was well attended, and great interest was taken in the projected scheme. Several leading members of the profession were present, and MM. Bouchard and Joffroy, his former pupils, made appropriate speeches and proposed the health of M. Charcot. The latter gentleman responded in graceful terms which were much applauded. M. Paul Bert, who was prevented attending the banquet, sent a letter of congratulation, which was read by M. Liouville, and as it is rather interesting in more than one point of view I send you an extract of it.

After apologizing for his unavoidable absence on such an auspicious occasion, he said: "Being a physiologist of the laboratory, I have no fetishism nor fanaticism, and I am far from believing that experiments on the living animals are productive of any physiological discoveries. The ephëbe history of science would protest against such an allegation, and the work of Charcot and his pupils, of his school in fact, is the most eloquent demonstration of the power of the means of action which a medical man can employ for the progress of physiology. It was in this point of view that I placed myself when I was called upon to give my opinion at the last competition for the membership of the Academy of Science.

Leaving aside the discoveries of a purely medical order, which M. Vulpian exposited with the greatest authority, I insisted on those which appertained to the science I cultivate, and, after M. Charcot, physician, I had to show up M. Charcot, physiologist. If it is true that science consists in the establishment of a constant relation between phenomena always antecedent, and others always consequent, it is not evident that it signifies little whether this relation is established in starting either from the one or the other of these orders of phenomena. The vivisectionists, who are impelled to the antecedent, in order, by means diametrically inserted, to the constitution of the science of pathological or normal physiology, it is all one. If the causes of error present themselves in greater number, more dangerous before the physician, he has the greater merit to avoid them and to arrive at a just conclusion."

The results obtained by the analyses of the various dietetic drinks and alimentary substances, at the Municipal Laboratory during the month of November is lamentably interesting and instructive, for, according to the official report of the analyst attached to the laboratory, almost every article of drink and diet in Paris is adulterated. Even the so-called natural mineral waters are not allowed exempt from the reproach of adulteration, as many of them are manufactured in Paris, so that those who drink these waters to avoid the water from the Seine are simply laboring under a delusion.

Apropos of adulterations I may mention that a new means of adulterating milk has recently been brought to the notice of the Lancet. The fraud consists of adding glucose to milk. The fraud in this case is the more easily practised, as the density of the milk is not affected, and the glucose imparts a sweetish taste to the milk which is rather pleasing than otherwise.

The French would do well to take measures effectively to correct or prevent the scandalous abuses so freely practised in their own country before we condemn the articles of food imported from other parts of the world. I have never been able to ascertain the real object or utility of the Municipal Laboratory in Paris, which is a recent institution, and kept up at an enormous expense. I am told that anybody could take anything to the laboratory, and for a small fee it has analysed. The analyst furnishes the applicant with the result of his analysis, but the latter is quietly told that the report given him is for his own private information or personal satisfaction, and that he cannot make use of it before a court of justice if he chooses to prosecute the miscreant.

You will remember the great sensation that was caused in the country by the importation of salted pork from America, which was condemned as always containing trichine. By a decree of February 18, 1881, importation was prohibited within the territory of the French Republic. But it was found that the poorer classes were the greatest sufferers by the prohibition, as salted pork constituted their principal food. Recent investigations have proved that under certain conditions the trichine could be driven out of the pork by good brine employed; there was no serious danger of trichinosis, even if the parasites abounded in the pork they are completely destroyed by cooking, on the report and recommendation of the Committee of Public Hygiene, who were consulted on the matter, the decree above referred to has been revoked.

Professor Minot having just published his quinquennial report, giving the numerical strength of the medical profession in France. The following table indicates the changes that have taken place since 1876, the date of the publication of the preceding report, and which is brought down to the end of 1881:

<table>
<thead>
<tr>
<th>Classification</th>
<th>1876</th>
<th>1881</th>
</tr>
</thead>
<tbody>
<tr>
<td>Doctors of medicine</td>
<td>10,743</td>
<td>11,643</td>
</tr>
<tr>
<td>Officiers de Sainte</td>
<td>3,633</td>
<td>3,203</td>
</tr>
<tr>
<td>Pharmaciens</td>
<td>6,232</td>
<td>6,443</td>
</tr>
<tr>
<td>Sages-femmes</td>
<td>12,847</td>
<td>13,493</td>
</tr>
<tr>
<td>Herbalists</td>
<td>983</td>
<td>972</td>
</tr>
</tbody>
</table>

It will be seen from the above table that there has been a marked increase in the number of doctors and of sages-femmes or midwives. In the Department of the Seine alone there was, in 1881, an increase of 555 doctors, 21 officers de santé, 30 pharmacists, and 395 midwives over the strength of 1876.

An official report, emanating from the Prefecture of the Seine, states that during the last ten years the number of lunatics furnished by the Department of the Seine increased to an alarming extent. There are at present 8,552 lunatics in this department, or 272 more than there were last year.

To Abort a Stye.—Dr. Louis Fitzpatrick writes to the Lancet that he has never seen a single instance in which the stye continued to develop after the following treatment had been resorted to: The lids should be held apart by the thumb and index finger of the left hand, or a lid-retactor, if such be at hand, while the tincture of iodine is painted over the inflamed papilla with a fine India-rubber pencil. The lids should not be allowed to come in contact until the part touched is dry. A few such applications in the twenty-four hours are sufficient.
A WESTERN DOCTOR ON THE DOCTORS OF THE WEST.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Allow me to briefly reply to Dr. Rafter's strictures on some statements recently published by me, under the heading of "Random Notes of a Western Trip." The letter of my censorious Old Code friend of Holton, Kan., in the West, places me in the uncomfortable position of him who, in the praiseworthy attempt to be clear, has only succeeded in making himself thoroughly misunderstood. For the astute Holton practitioner imputes to me a mean opinion of Western doctors, whereas I had endeavored to point out wherein consisted their superiority over some of their Eastern counterparts. In other words, where I intended praise he thinks he has discovered obloquy and censure. Now a correction of the errors which Dr. Rafter has fallen into, for himself alone, would savor too much of a deliberate attempt to make much ado about nothing. I should never have asked the privilege of your columns for so insignificant a matter, but Dr. Rafter has unnecessarily elected himself the champion voice of "the sentiments of nine-tenths of the profession of the West." He has "something of an acquaintance among the profession," and having "looked up the statistics" is able to "come near at it." Such eminent qualifications naturally constitute a clear title to the assumption of the duties of a responsible representative of the general sentiment of the profession. It is, therefore, in his capacity of mouth-piece for the Western doctors that I propose to offer Dr. Rafter a little explanation.

While travelling in the Northwest I received certain impressions, from conversations with physicians and otherwise. Among other things I thought I perceived a tendency for the Nueva Medicina of the Code than has for some time been customary in New York. Strictly personal feelings in the matter prompted the expression of my preference for the apparently peaceful condition of the professional life of the West, as compared with our Eastern bellicose attitude. But between such purely personal impressions, not yet ripened into immutable conviction, and actual facts it is quite possible that there may be a wide difference. I never claimed that my impressions were anything but impressions, and I am very willing to stand corrected by one who speaks with the statutory authority of Dr. Rafter. Accordingly I am now to believe that the West knows and cares more about the Code than the East. But I have no doubt in my mind that the particular Western doctor whom my critic alludes to "can quote from the lectures of Flint, or Loomis, or the venerable Alonzo Clark as readily." The deplorable fact is, the Eastern practitioner cannot "quote readily" at all in that direction. Moreover, I fully concur in Dr. Rafter's opinion that "they (meaning the Westerners, I presume) can practise medicine as intelligently and surgically as successfully as practitioners of the same ability there" (meaning the East, I suppose). So they can. What's to hinder them? And, by the way, they practise as well as they know how to in Timbuctoo, or the moon, for that matter. Let me respectfully enquire what has the ability to quote authorities and to practice just as well as one knows how to, what has that to do with one's knowledge and appreciation, ignorance or contempt of the Code?

And since the question of specific ability has been broached, which is a subject as remote as possible from Code contentions, let me hasten to assure my critical friend that, after all, we have a larger proportion of skilled and inquisitive doctors than can possibly be found in the West. Dr. Rafter ought to have known, before being told, that there live, for example, right here in the city of New York, more world-famed leaders of the mind medical, more eminent specialists in the various departments of medicine than he can collect in all the great Northwestern region from St. Paul to Portland. It is no disparagement of the intelligence and learning of the Western doctors to admit this plain truth. In the nature of things it could not well be otherwise. As for the standing of the general practitioner it is quite likely true that the Western doctor is as good as the same kind of a doctor anywhere else. But it was hardly necessary for Dr. Rafter to submit this startling novelty to our consideration.

Respectfully yours,

EDMUND C. WENDT, M.D.

12 West Thirty-Fourth Street,
New York, December 31, 1885.

THE EDUCATION OF THE LAITY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: A much-needed reform is the adoption of some means by which we can counteract the growing heresies and skepticism about the practice of medicine. The seductive advertisements of quacks and patent-medicine vendors create this condition of the public mind. They improve every opportunity to bring themselves and their wares to favorable notice. We do not.

The religious and secular press teems with such literature, drug stores dispense cures of it, and we beheld the humiliating spectacle of an unsuspecting clergy consenting to become the patrons of the leged virtues of the many patent and proprietary nostrums that flood the land. Everywhere, from the darkest recesses of the vilest water-closets to the rocky facets of the grandest mountain scenery, the hand of quackery with pate and paint has "got in its work."

The first efforts of the child to practically apply its meagre knowledge of letters is to try to decipher these miserable blotches that deface and disgrace our fair landscape. Need we ask "What shall the harvest be?" There is no disguising the painful fact that the people are running after strange gods. To expostulate, to weep and wail and gnash our teeth, to find fault, and to set up a pharisaical standard of "I am holier than thou" will only make bad matters worse. The question, then, naturally arises, what can be done? What steps can we take to counteract the evil? It is easy to find fault, and those doing so should always propose something better, and the proposition to be valuable must be practicable as such. We submit that the medical profession must educate the public in their own interest. How? We answer first, by popular lecturers.

As to the first method we confess that we cannot at all times get the ear of the masses, but we can attract them through others; for instance, through college classes, teacher's institutes, agricultural and horticultural societies, beekeepers' and dairymen's associations, etc. In an adjoining county it has been the custom for a number of years to hold an annual joint session of the Teachers' Institute and the County Medical Society. This session lasts two hours and is addressed by some member of the profession of acknowledged skill and ability as a lecturer on such popular subjects as "The Germ Theory," "The Human Hand," etc.

These lectures have become the occasion for a popular gathering of the people, every seat and available inch of standing room in a large hall being occupied. On one occasion at which the writer was present an ex-Member of Congress, one of the most substantial citizens of the county, become so interested that at the close of the lecture he arose from his seat, and by way of eulogy said, "That lecture is the best thing I ever took from a doctor." The situation here is that the doctor has tendered the doctors in general and the lecturer in particular, and everybody was convinced that the regular profession in point of scientific attainments was without a rival, and justly merited the patronage and confidence of the public.

C. It is needless to say that the thousand-and-one "cure-
THE MEDICAL RECORD.

Army and Navy News.

Official List of Changes and Duties of Officers of the Medical Department, United States Army, from December 29, 1883, to January 5, 1884.

APPLET, DANIEL M., Captain and Assistant Surgeon. Having relinquished the unexpired portion of leave of absence granted by S. O. 68, Headquarters Division of the Atlantic, November 16, 1883, and reported for assignement, assigned to duty at Fort Porter, N. Y. S. O. 247, par. 2, Department of the East, December 29, 1883.

HAVARD, VALERY, Captain and Assistant Surgeon. Assigned to duty in charge of office of Medical Director, Department of Texas, during the temporary absence of that officer. S. O. 164, par. 2, Department of Texas, December 31, 1883.

Official List of Changes in the Medical Corps of the Navy, for the week ending January 5, 1884.

HUDSON, A., Medical Inspector. From duty as an Assistant to the Bureau of Medicine and Surgery, on the 18th inst., to the U. S. S. Lancaster, as the relief of Medical Inspector N. L. Bates, who is to be detained ordered home.

RUSSELL, A. C. H., Passed Assistant Surgeon. From the Navy Yard, Washington, to hold himself in readiness for sea service.

Medical Items.

CLINICAL NOTES BY THE WAY.—Dr. J. S. Prettyman, of Milford, Del., sends us a number of items of practical interest:

Clinical thermometers.—Many of your readers seem to be in trouble because of the fact that thermometers are so often broken. Why, do they not know that this is just what they are made for? Hence they encase them loosely in hard, unyielding cases, so that a little bang or jar shall snap them against the unyielding case. If it could be made to their interest to do so they would, no doubt, line the cases with a soft, elastic cushion, into which the delicate little instrument could be gently forced, and thus made to repose in a soft, elastic bed, in which they would be safe from all ordinary accidents.

New Remedy for Burns.—During a recent visit to a patient in an adjoining town, I was hastily summoned to see a woman badly burned (while lighting a fire with coal oil) on the hands, arms, and around the body where her clothes were fastened to her person. Not having any of the ordinary remedies at hand, except cold water, which, en paucis, is one of the best where it can be properly applied, I mixed hog's lard with four times its weight of common bread soda (the bicarbonate), which

F. H. DARBY, M.D.

Moscow, O., December 30, 1883.
is used here in the homes of many for mixing with the dough in bread-making, and applied it as a salve to the burned parts, and I never saw a case of the kind do better under any treatment. The wounds were kept well covered with it, and they all healed very nicely without inflammation and with very little suppuration. Indeed, they seemed to dry up under it. I shall try it in the future in all similar cases, until I find something better.

Antiseptic.—For twenty years or more I have been in the habit of closing up all fresh wounds, that were clean or could be made clean, and that were not extremely ragged, with bandages kept well saturated in the following:

B. Powd. myrrh. § viij.  
Powd. capsic. 3 j.  
Ol. anisi. § ss.  
Alcohol. O. iv.  

M. Make a tincture which I call tinct. myrrh comp. If the bandages are saturated with it they form, with the gum, a nice case all around and over the wound, and retain the parts in situ in an excellent manner. No treatment that I have ever used or seen used by others seems to me to be quite equal to this in the excellence of the results. It appears to keep down inflammation, prevent suppuration, pain, and soreness, and greatly to promote the healing process. Lately I have improved the preparation as follows:

Tinct. Myrrh Comp. cum Benzoinum.  

B. Powd. myrrh. § viij.  
Powd. benzoin. § iv.  
Powd. capsic. 3 j.  
Alcohol. O. iv.  

M. Make a tincture, and use as above indicated.

This treatment of suitable wounds I can recommend in the highest manner. Twice a day the dressings should be saturated and no change made in them for a week, unless untoward symptoms make it necessary. When the dressings are to be changed, saturate them well with alcohol to soften the gum, so that the bandages will not adhere.

Vinum lobelia comp.—For more than a quarter of a century I have used a preparation under the above title, which has become a household remedy throughout all this section of country. While perfectly safe, it is used as an emetic, febrifuge, carminative for colic in infants, and to promote sleep; also for coughs, colds, etc. When given in moderate doses it soothes the system, allays fever and nervous irritation, promotes perspiration, and quiet sleep. When worst you can do with it is to produce emesis, which it most certainly does if given in quantities large enough, while at the same time it is sufficiently stimulating to prevent the tendency of the drug to relax and prostrate. The preparation is made as follows:

B. Powd. lobelia inf. 3 j.  
Powd. American valerian (cypripedium pul.) 3 j.  
Powd. peppermint.  
Powd. ammonia 33 3 ss.  
Sherry wine. O. j.  

M. Let the mixture stand for a month or more in a warm place with frequent agitation. Filter when required for use.

The dose is from ten drops for a very young infant to a whole teaspoonful for a child three years old, mixed in a little hot water sweetened, or some simple herb-tea. The dose may be repeated as often as thought desirable, or increased or lessened as needed; always resting in the fact that emesis is the worst it can do. When used for coughs, colds, etc., it may be made into a syrup by mixing with simple syrup in any quantities or proportions desired. In my own family, and many others under my professional care, this remedy has superseded all anodynes, cough syrups, croup remedies, etc., and the chil-

dren—ten in my family—have been raised on it. When used for larger children, for fevers or as an emetic, plenty of warm herb-tea—catmint, pennyroyal, sage, etc.—as the vehicle, aids both the diaphoresis and the emesis, as vomiting is always easy on a full stomach, but more difficult on an empty one.

Corrosive Sublimate in the Treatment of Diphtheria.—Dr. H. T. Hanks of this city, writes: "I wish to call the attention of the profession, through your columns, to a therapeutic agent in diphtheria, which in my hands has served me better than any other remedy. I refer to corrosive chloride of mercury. I have used it in all cases which have come under my observation for two years. There has been no prevailing epidemic of this disease in New York in that time, but I had eleven cases in families which I attended. In all of these cases I have been well pleased with the effects of minute doses of corrosive sublimate in solution, and I believe it to be the most valuable medicine at our command in this disease. I have no theory to advance to account for its well-known power of destroying living germs. I have used the remedy in doses of 1/100 of a grain in wine in the morning and at night and day. In my last two cases, I have had even better success by using the medicine with a common hand atomizer. I have been agreeably surprised at the rapidity with which the exudation disappeared under this treatment. My formula for inhalation by hand atomizer is the following, viz.:

"B. Hydrarg. chlorid. corrosiv. gr. ij.  
Glycerine. j.  
Alcohol. O. viij.  
"M. Sig.—To be used with atomizer for three to five minutes every half hour.

"There is no necessity of giving the sublimate in any other form while this treatment is pursued. I insist, of course, upon thoroughly disinfecting the sick-room by the usual means at our command, and over and above this I have generally used Hoffman's Anodyne in small doses. But I am convinced that the corrosive sublimate has done more for me than all other means combined."

Surprising the Urethra.—"In urethral stricture I have," says Dr. M. Diday, "in order to avoid confounding grains of a drug, put one (1) drachm of water in the urethra at night and day. In my last two cases the stricture disappeared entirely. When the end of the sound is in contact with the coarctated portion of the canal I suddenly put the following question to the patient: 'How long is it since you have been with a woman?' If it is a simple spasm the sound immediately enters."—Medical Chronicle.

Royal Doctors.—The prince physician, Duke Charles Theodore of Bavaria, M.D., has been promoted to a lieutenant-general by the king, but will not take any active part in military matters. A second scientific scion of the Wittelsbach family, Prince Louis Ferdinand, recently married to a sister of the King of Spain, has in press a monograph of comparative anatomy on the human and animal tongue, with upward of a hundred illustrations. He made the investigation for his work partly in the anatomical institute of Professor Rediker, partly in his own laboratory at Nymphenburg Castle.

Cure for Cramp.—"The simplest and best method, says the editor of the Pacific Medical and Surgical Journal, is a bandage applied above or below the knee, preferably the former."

How to Keep a Hypodermic Syringe in Order.—Dr. Frank W. Epley, of New Richmond, Wis., writes: "Get a good one with a nickel barrel, graduated on piston-rod, and with the hole in the barrel beveled on inside, so that you can remove the piston, spread the leather valves, and, owing to the beveled edge of the barrel, return it with ease in perfect condition. A lachrymal syringe with a point adjusted makes a royal syringe."
STATISTICS OF FOUR HUNDRED CASES OF RHEUMATISM, WITH ESPECIAL REFERENCE TO TREATMENT.

TREATED AT THE ROOSEVELT HOSPITAL.

BY CHARLES H. MAY, M.D.,
MT. SINAI HOSPITAL, NEW YORK.

INTRODUCTION.
The following pages present statistics, derived from the study of the histories of four hundred cases of rheumatism, acute, subacute, and chronic, treated at the Roosevelt Hospital.

These are unsolicited cases: they are, in fact, all the cases which have occurred at this institution, from its opening, to September, 1882, a period of over ten years.

Muscular, gonorrheal, and syphilitic rheumatism, as well as rheumatoid arthritis, have been omitted from consideration.

The order in which the various items have been classified is as follows:

An enumeration of the histories of all the cases is first given. In these histories, all the items of interest, and all those relating to, or forming a basis for subsequent statistics are given. Then follow:

A. Tables showing the number of cases treated in each year.
B. The relative frequency of attacks in different months; a, dating from time of entrance into the hospital; b, dating from commencement of attack, as learnt from the history of the patient.
C. The maximum temperatures and condition in which patients were discharged.
D. The relative frequency of attacks at different ages.
E. The duration of joint-symptoms before and after entering hospital, of the pyrexia, together with the treatment employed and the condition in which the patient was discharged, the cases being grouped, according to the maximum temperature reached.
F. The same, in which only the cases which left the hospital cured are given; here the cases are grouped according to the treatment employed, and subdivided according to the maximum temperature reached.
G. N. Comparison of the results obtained by different methods of treatment.
H. Unpleasant effects produced by the various drugs used in the treatment — salicylicism, iodism, etc. — their relative frequency and nature.
I. Comparison of the efficiency of salicylic acid, given in capsules and in solution, respectively.
K. Relative frequency of the cardiac valvular lesions in rheumatism.
L. Relative frequency of association of two or more cardiac lesions.

T. Liability to heart complications from rheumatism at different ages.

U. Relation of the occurrence of cardiac complications to the severity of the attack, as judged by the maximum temperature.

W. Frequency of relapses.

Explanation of Remedies and Doses. — Salicylic acid, from the time when first used until February, 1879, was administered in solution; after this date in capsules. The dose in which it was given, unless otherwise mentioned, was ten grains every two hours at first, gradually increasing the intervals of its administration to three and four hours, and then giving it only three times a day, as the pyrexia and joint symptoms subsided; its use being persevered in, however (Gr. x. t.d.), for some time after the symptoms had disappeared.

The dose of Rochelle salt was one drachm three times a day; of the iodide of potassium it was ten to twenty grains three times a day, and of the wine of colchicum and iodide of potassium it was ten to twenty grains of each three times a day, unless otherwise stated.

In the report of the treatment, when two or more drugs have been used at the same time, the names of these are connected by "and." When one drug was used after the other had been discontinued, the names of the two are separated by a period. This also applies to external remedies.

No abbreviations have been made use of, excepting the employment of the letters C, I, and U, which represent cured, improved, and unimproved, respectively, referring to the condition in which the patient was discharged from, or left the hospital.

All temperatures are axillary.

Unless stated to the contrary, all heart complications already existed at the time when the patient entered the hospital.

Much has been said and written against statistics, and this prejudice is not without foundation. Our medical journals are flooded with deductions based upon the observation of too small a number of cases, and are apt to be biased by the fact that the writer very often compiles his statistics to favor his version of facts remaining to be proven.

No one will claim perfection for statistics, however complete they may be; but when the number of cases drawn from is large, and the writer does not start out with the intention of proving or disproving any one version or opinion of disputed matters, no such great objection can be made to such statistics.

All that has been attempted in these pages has been to state facts as they were found in the records of the hospital, and to compare and tabulate these facts, and very few deductions have been made.

The histories of the cases employed were taken by a number of different observers, all properly qualified, as the high standard of the competitive examination for appointment to the resident staff of this hospital proves, and the histories having been taken thus, by such a large number of persons, the chance of their being biased is absent.

In concluding this introduction, the writer wishes to acknowledge his indebtedness to Dr. William H. Draper, of the attending staff of the Roosevelt Hospital, for his kind permission to use the hospital records for the purposes of this thesis.

ON CONIUM IN MALARIAL DISEASES.

BY RICHARD C. NEWTON, M.D.,
ASSISTANT SURGEON, U. S. ARMY.

No physician whose practice lies in a malarious locality can fail to take interest in the papers of Drs. McDaniel,1 Webb,2 and Minor,3 recently published in the Medical News, relative to the safety and efficacy of quinine in hemorraghic malarial fever. Dr. McDaniel makes, as it seems to me, an admission very damaging to his theory in his first paper,4 viz., that he only resorted to the hypodermic use of quinine once in his cases, and is disposed to give the method a further trial, and this alone would seem to give color to Dr. Webb's belief, that the methods of administering quinine, made up of its detractors, rather than the drug itself, are to be blamed.

In Reynold's Practice5 it is said: "The late Dr. David Blair, Surgeon-General of British Guiana, thus expresses himself on the question of the safety of quinine: "It has been prescribed by me to patients of both sexes and all ages; and where ascertainable, almost invariably to cinchonism, during thirteen years, and probably to the extent of several thousand ounces of the sulphate, and during that time I have seen no danger from its effects, with the exception of the occasional occasional abortion."" Also on the same page Dr. Davy says, "that in the remittent fevers of the West Indies, during the first quarter, after the practice was introduced of giving quinine in full doses to cinchonism, out of 165 cases only 2 proved fatal; and the record of the post-mortem examination in the two fatal cases shows that they were rather instances of liver congestion than of fever of the true remittent type." Stronger testimony than this it would be hard to find, although references might be added indefinitely. It is not reasonable to suppose that a number of hemorrhagic cases did not occur in the practice of either of these gentlemen.

The review of the prominent modes of treatment of remittent fever by the most eminent of British army surgeons has led Sir Ranald Martin to make the following general remark,6 namely, that a disease so varying in its nature, so general and complicated in its influence on the system, is not to be justly treated by one remedy, Bark and camomile, each a remedy of great power, will sometimes be needed, and are and always have been extensively used. Any other alleged adjuvant to the invaluable alkaloid merits a fair trial, because it may increase our means of battling with a miasm, which "has been estimated to cause one-half the mortality of the human race."* 

During the past nine months 269 cases of malarial diseases have occurred among the officers and enlisted men of this garrison, besides a large number among the citizens, and the women and children in and near the post. Many of these cases have been reappearances of the poison in the same person. Not a single case of uncomplicated malarial fever has proved fatal. And the writer believes that it is his good fortune to be in a position to recommend to the profession a drug of considerable value in the treatment of malarial poisoning, that is not, so far as I know, generally so used. The prominent medical journals for the past six years do not, to my knowledge, contain any reference to the use of conium in malarial disease. Nor do the text-books at my command have much to say about this drug, and nothing about its value as an antiperiodic. Conium seems to have fallen into disuse, and perhaps it is one of the good old drugs that deserves to be revived. Dr. E. C. Seguin seems to esteem it, and to give it in doses considerably larger than those laid down in the textbooks. There seems to be no doubt that the drug has a powerful action on the ganglionic system of nerves.

Dr. Stillé tells us7 that conium was strongly recommended by Fothergill in neuralgic and rheumatic affections, especially for the former, and that it has been successfully used in insanity. It used to have a reputation as a cancer remedy, etc. At all events, it has alleviated pain and has acted as a tonic.8 Its uncertainty of strength is everywhere spoken of, and this has, no doubt, helped to bring the drug into discredit. It seems probable, however, that with the greatly improved pharmacy of the last ten years uniformity of results can in some measure be brought about by conium, or its alkaloid, conia, can be always obtained.

Dr. Tilt9 asserts that "in agues the ganglionic system is the prime motor," and "the central ganglia feel the first shock of the cholera poison, when, during a severe epidemic, a man walking about in good health, suddenly feels nausea, drops down, and dies." Persistent intermittent fever of ague origin has often been of a similar way.

The epigastric pain in malarial affections which Dr. Holt says10 was pointed out to him by Dr. J. H. Ripley, I have often noticed in patients of all ages. Dr. Webb attributes the hematuria in hemorrhagic malarial fever to vasomotor disturbance. The inference is allowable that the epigastric pain is attributable to irritation of the epigastric ganglia of the sympathetic nervous system. It hardly seems necessary to multiply references;11 we may take it for granted that, if the ganglionic system is not the prime motor in agues, it is very seriously disturbed, and that medication should be directed toward regulating the functions of the cerebrum abdominale, as well as toward a sweeping out of this long and narrow passageway (the alimentary canal) with emetics and cathartics, a method of sanitary policing which had great credit with our predecessors, and is perhaps not sufficiently employed at the present day."

During the summer and spring of this year I have used repeatedly the following prescription:

B. Ext. conii fl. 30 cc. 5 j.
Ferri perox. 3 ii.
Spts. vini gallici 5 ii.
Quin. sulph. 3 ii.
Syr. simp. 3 ii.
Ol. menthae pimpinellae 3 ii.
M. Sig. 3 j. q. four hours until two hours before chill is expected, then q. two hours for two or three doses, then q. four hours.

To children it has been given very successfully by doubling the amount of syrup.

This prescription was given me by my friend Mr. F. O. Vaille, of Denver, Col, who had it from his father, the late Dr. Vaille, of Springfield, Mass. The remedy is known hereabouts as "Vaille's disease," and with the same degree of local popularity. Dr. Vaille's medicine is not a perfect solution, and for this reason, as well as for those already given, a more elegant preparation of

4 MEDICAL RECORD, December 2, 1887, p. 632.
6 See also J. F. Fayrer's Croonian Lectures, op. cit.
7 Dr. Stellé, in MEDICAL RECORD, September 16, 1884, p. 517.
It will be observed that there is a small quantity of quinine in the mixture, so that each dose of the remedy contains about two-thirds of a grain of quinine. Mr. Vaille has told me that his father used to think that the remedy was probably as efficacious without the quinine as with it. I regret that I have not tried the prescription without the quinine. I have used it, or one very similar, without the conium, and have, generally speaking, accomplished little with it.

That there may be a more palatable and more artistic way of administering conium, or any or all of the drugs found to be essential in Dr. Vaille's formula I am quite hopeful. The remedy acts as a mild laxative, diuretic, and tonic. Its quieting and soothing effects differ widely from the disturbance often occasioned by quinine, and it naturally acts very beneficially when cinchonism has been produced. As the preparation is not likely to be vaunted as a beverage, owing to its pungency, its habitual abuse is not a probable evil. I do not know that dilution with water impairs the efficiency of the medicine, but have generally recommended that water be not taken with it. To direct that water be not used during the administration, as is done with Warburg's tincture, is of course, out of the question.

The formula given for Warburg's tincture in the New Remedies for August, 1852, is not, considering the supposed physiological actions of the various ingredients,* worth much attention.

Although the latter ought not to be a cheap preparation, it is considerably less costly than an equivalent amount of quinine. It possesses the advantage over Warburg's tincture that it is safe, so far as my experience goes (and I myself customarily take twice the prescribed dose), whereas Dr. Maclean, in "Reynolds' Practice," says the administration of Warburg's tincture is never, in a dynamic case, unattended with danger.

If any physician will make a trial of Dr. Vaille's medicine, more especially in an "obstinate case of malaria," and make known the result of the experiment, it will greatly please me, and I trust that the observations will prove of general benefit.

Port Said, Indian Territory, December 14, 1853.

THE USE OF ELECTRICITY IN CHOREA.—Dr. C. L. Dana writes: "Allow me to say a word in reply to Dr. Rockwell's criticism of my article upon anodal galvanization of the brain in chorea. The article in question did not appear in THE MEDICAL RECORD, as Dr. Rockwell states, but in the Medical News, and so far from ignoring Beard and Rockwell's experience, mention is made of it twice, as Dr. Rockwell would see if he had read the original paper. The priority in the use of central galvanization in chorea is ascribed to Benedikt by Beard and Rockwell themselves (p. 455, ed. 1871). Dr. Rockwell, in 1881, recommends general faradization, central galvanization, and the ascending galvanic current, with special reference to chronic chorea. His recommendations are quite different from what I proposed, viz., stable anodal galvanization of the brain with gradually increasing and decreasing strength of current in acute chorea. Central galvanization does not include this, and there are no facts on record which show that an electrode over the epigastrium produces any especial effect upon the solar plexus. I much regret that Dr. Rockwell has hastily assumed that I would ignore his work."

MR. BRODHURST'S VIEW OF THE CAUSE OF ROTATION IN LATERAL CURVATURE OF THE SPINE.

By A. B. JUDSON, M.D.,
ORTHOPEDIC SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL.

In the third edition of his valuable work on curvatures of the spine Mr. Brodhurst has advanced a theory of the cause of rotation which fails to throw additional light on this feature of lateral curvature. The following passage presents his view:

"So soon as spinal curvature commences the axis of the trunk is changed, and the column is no longer poised in the vertical line on the heads of the thigh-bones. The superincumbent weight being no longer transmitted in the normal axis of the trunk, but falling on the side of the concavity of the primary curve, unequal pressure causes first compression of the intervertebral substances which enter into the curve. After a variable time this compressed condition of the intervertebral substance continues more or less, and is not removed by ordinary recumbency. The body of the vertebra then begins to move laterally, through the pressure on the inner, or concave side of the curve, and in consequence of pressure being removed from the convexity. And through this compression on the side of the concavity, a gliding, or rotating (lateral) movement of the body through the intervertebral substances is established. This compression acts first on the intervertebral substance, and secondly on the body of the vertebra; and causes thinning and lateral displacement, or rotation (curvature). Rotation (Curvature), then, is immediately due to abnormally increased pressure on the concave side of the spinal curve, and to removal of pressure from the convexity."

I have ventured to Italicize certain words in the above passage and to insert other words parenthetically, in order to show that by omitting the words in Italics and substituting those in parentheses the passage becomes an exposition of the mechanics of simple curvature without rotation. It thus appears that the above explanation of the cause of rotation is essentially an explanation of the mechanics of lateral curvature with the question of rotation omitted.

If, however, to the above passage, altered as indicated, we append the statement that the motion of the bodies of the vertebrae is greater than that of the spinal processes because the processes of the body are embarrased in the parietes while the bodies are further displaced laterally, but the cavity of the trunk, this movement constituting rotation, as proposed by me in 1876, we have at once a statement of the mechanics of lateral curvature and an exposition of rotation on grounds which are correct and scientific.

Before my attention was called to the fact by Mr. E. Noble Smith 1 I was not aware that this method of explaining the cause of rotation had been employed by Mr. Rogers-Harrison in 1842. His words are as follows: "To conceive the cause of this extraordinary mode of derangement it is necessary to imagine that in a well-marked curvature of the spinal column continuing to support the weight of the body, the vertebrae of the middle of that curvature are, in fact, in the same position as if they were urged by a direct and horizontal force on the side of the concavity, towards that of the convexity. In this impulsion the body of the vertebra, isolated in its anterior and lateral parts, experiences no resistance; but the articular processes are powerfully restrained by their reciprocal traction. These processes find in their articulation with the tuberosities of the ribs resistance to their deviation, which would be very weak on the part of an isolated rib, but which becomes considerable by its union with the adjoining ribs. It results

3 Brodhurst, op. cit., pp. 493, 494.
The recent discovery of important facts in the anatomy of the nervous system has been largely due to the application of certain methods of research. Among these methods that of Flechsig has been productive of most reliable results. It will be remembered that Flechsig discovered, in 1876, the fact that in the fetus the development of the nerve-fibres and of their medullary sheaths follows a definite law, various nervous tracts developing their sheaths at various times. By examining brains and cords at different stages of development it was therefore possible for him to trace special tracts along their course, as each tract presented a characteristic appearance which distinguished it from all others. The result of this new method was to divide the white matter of the spinal cord into a series of columns, and the supposition that each of these columns differed in function as well as in time of development has been confirmed by physiological research.

In 1881 Flechsig applied the same method to the investigation of the nervous tracts in the brain, and having completed his observations, he has recently (August, 1883) published a "Plan of the Human Brain." This contains a statement of the course of the groups of nerve-fibres from the cortex to the periphery and between the various parts of the central and peripheral nervous system. Independent investigations regarding the tract of secondary degenerating fibres have led to conclusions which agree remarkably with these discoveries of Flechsig. They are therefore doubly worthy of note. His conclusions are as follows:

1. There exist direct nervous tracts between the different parts of the brain and between the brain and spinal cord. The motor tract arises from the cortex of the parietal lobe (including both central convolutions). The anterior limit of the motor zone of the cortex is the sulcus precentralis. The posterior limit is less clearly defined and reaches probably as far back as the paracentral lobule, the anterior part of the paracentral lobule, and the precentral convolution (with the exception of the anterior portion of the anterior central convolution, which is in connection with the cranial motor nerves, especially with the facial and hypoglossal) are connected with the motor nerves of the body by means of the "pyramidal tracts." The course of the pyramidal tracts is direct and they have no connection with the basal ganglia or with the cerebellum, but pass to the spinal cord; in the posterior part of the internal capsule the pyramidal tracts lie in the middle third; in the crus cerebri in the median portion of the outer half; and in the medulla. Each tract divides into a small direct pyramidal tract lying in the anterior median column of the same side, and a large crossed pyramidal tract lying in the lateral column of the opposite side. Nerve-fibres from these tracts constitute a substance of the cord of the side on which they lie, and are connected with the large multipolar ganglion cells. The greater part of the pyramidal tracts go to the motor cells of the cervical and lumbar enlargements and hence connect the motor area of the cortex with the extremities.

2. Certain direct sensory tracts at present determined are three:

First. The olfactory tract, from the olfactory bulb, divides into three parts: (1) the first passing to the base of the frontal lobe, probably to the gyrus fimbriatus; (2) the second to the cortex of the gyrus uncinatus; (3) the third passing backward through the lamina perforata anterior to the posterior part of the internal capsule, where it is lost.

Second. The optic tract, made up of fibres from both optic nerves, passes (1) to the corpus geniculatum externum, from which fibres radiate outward through the posterior part of the internal capsule of the same side to the corona radiata; (2) to the anterior corpus quadrigemini, with whose gray cortical zone it is in direct connection to a much greater extent than with the white matter beneath it. This tract then turns back upon its own course, and passing over the corpus geniculatum externum joins the radiating fibres from that body before mentioned. This bundle of radiating fibres passes backward on the outer side of the posterior cornu of the lateral ventricle to the visual area of the cortex which lies in the cuneus and occipital lobe.

Third. The sensory fibres from the skin pass from the spinal cord and pass through the tegmentum of the crus cerebri, through the posterior part of the internal capsule, which lies between the pyramidal tract and the corpus geniculatum externum, and upward along the outer and upper margin of the sides of the optic thalamus in the corona radiata. Their termination is in that portion of the cortex which lies between the sulci precentralis and the anterior part of the occipital lobe. The cortex which lies beneath the parietal bone is the portion in which the sensory fibres from the skin terminate.

3. There exists a system of nerve-tracts in connection with the optic thalamus.

First. The corona radiata is largely composed of nerve-fibres which pass outward in all directions from the external surface of the optic thalamus and connect it with all parts of the cortex. The cortex of the frontal lobe is joined to the optic thalamus by means of fibres which pass through the anterior part of the internal capsule and upward along the outer and upper margin of the sides of the optic thalamus and to the striatum and to the stratum zonale. The parietal cortex in its entire extent is joined with the thalamus by fibres which pass to the outer and inner nuclei and to the stratum zonale. The cortex of the temporo-occipital lobe sends a large bundle of fibres to the pulvinar (the posterior part of the optic thalamus) and to the stratum zonale. The cortex of the inner nuclei of the thalamus and with the striatum and to the striatum zonale. The cortex of the hippocampal region joins the anterior nucleus of the thalamus by means of the fornix, which, passing first to the corpus mammillare, turns upon itself and then ascends. The lenticular nucleus sends fibres through the internal capsule to the optic thalamus, but whether these end in the thalamus or pass down to the tegmentum is undecided.

Second. A second series of tracts connect the thalamus with the crus cerebri and its tegmentum. 1. Visc d'Azry's bundle of fibres, passing downward from the anterior outer nucleus of the corpus mammillare, thence turns upon itself and sends some fibres to the corona radiata (already described) and others downward and backward between the red nucleus and the substantia nigra of the tegmentum to the formation reticularis of the medulla.

2. Meynert's bundle is made up of fibres coming from the stratum zonale of the thalamus, from the ganglion thalamicum and from the gray matter lining the third ventricle, which unite and pass through or near the red nucleus, are then connected with the ganglion interpe-
under the gray matter of the fourth ventricle and consists largely of association fibres between the various cranial nerve-centres, especially between the third, fourth, and sixth nuclei. Inferiorly this bundle can be traced into the anterior columns of the cord, and superiorly it reaches to the gray matter of the third ventricle. It is the first tract to develop in the fetal brain.

Fourth.—The formatio reticularis contains numerous longitudinal fibres whose connections are still unsettled. Some arise from the corpora quadrigemina and pass downward. Others pass upward from the posterior columns of this cord.

Fifth.—Several of the tracts above described, viz.: the second division of the superior peduncle of the cerebellum, the smaller division of the lemniscus, a few fibres from the posterior longitudinal bundle, and the ascending fibres from the formatio reticularis, unite at about the level of the corpora quadrigemina, and are joined by fibres coming from those bodies. The mass of fibres thus formed passes into the posterior part of the internal capsule and spreading outward opposite the third of the optic thalami radiates upward and backward and outward toward the cortex of the parietal and temporal regions and toward the posterior region of the thalamus striatus, especially the tegmentum of the thalamus striatus. As a whole it is parallel to the pyramidal tract from the cortex to the periphery, but lies posterior to this in all its parts. Its fibres degenerate upward from the site of any lesion, while those of the pyramidal tracts degenerate downward from the site of a lesion. Its fibres are isolated by medullary sheaths at a later stage of their development than those of the pyramidal tracts. For these reasons Flechsig considers this as the general sensory tract from the periphery to the cortex, while the pyramidal tract is the motor-path from the cortex to the periphery.

This plan of the human brain differs in some respect from that of Aeby, of Bern, and also from that of Wernecke. In regard to the most important tracts, however, they all agree, and the results of Flechsig may be accepted as the outcome of careful research by means of an original and trustworthy method of investigation. Any work which promises to make the complex subject of the anatomy of the brain more clear and simple demands the close attention of all. The anniversary should be called upon by the authorities of tracing tracts between various centres by means of the order of their development, and of the direction of degeneration, has cleared up many doubtful points and brought order out of confusion.

PERFORATING DUODENAL ULCER, AUTOPSY.—Dr. F. B. Streeter, of Glens Falls, N. Y., sends the following history: "Mrs. Mary E. C——, a native of this State, aged forty-five years, was taken the morning of December 31, 1883, with a severe attack of vomiting, in which the contents of her stomach were ejected, and, finally, a considerable amount of blood. She soon became collapsed, unconscious, and died at 4 P.M. on the same day. On examination by the Coroner, who performed twenty-four hours after death, was made by direction of a Coroner. The brain and thoracic organs were normal. Nothing was found in the stomach except a few ounces of blood. There was some slight thickening and contraction of the pylorus. The first third of the duodenum was thickened, showing three puckered cica- trices, and it was surrounded by old and very tough adhesions of the peritoneum, which had evidently proved useful in prolonging life at some previous time. At the lower end of the first third of the intestine there was an ulcer the size of a dime, communicating freely with the free cavity of the peritoneum. The history of the case, as far as it could be learned, is like that of any similar ulcer of the stomach. There was no evidence of her having had any constitutional disease, the remaining organs of the abdomen being in a healthy condition."
CASE OF BELLADONNA POISONING RESULTING FROM THE APPLICATION OF A BELLADONNA PLASTER.

By MARTIN J. FLEMING, M.D.,
NEW YORK.

I was hastily summoned, on the morning of December 19th, to see J. R., aged forty-three years, machinist, a muscular, well-developed man, of temperate habits, and robust physique.

I was informed that, just previous to my arrival, a diagnosis of insanity had been made, and the patient's removal to the Pavilion for the Insane at Bellevue was complete.

I found the patient in a condition of great restlessness and excitement, moving about his room with a staggering, uncertain gait, and complaining chiefly of vertigo and weakness. His pupils were dilated, his vision indistinct, and he seemed unable to recognize even any member of his own family. When he attempted to seat himself on chair or sofa, he appeared to miscalculate the distance and would fall to floor in sitting posture unless supported. He was delirious; and his delirium was of a mournful character, unless his movements were checked or interfered with, when he became violent. He imagined for the most part that he was in his shop and guiding his machine. At first sight I would have supposed that I had to deal with a case of alcoholism, were it not that his temperate habits excluded that supposition.

He was very thirsty. His voice was husky, and he spoke only in a loud whisper. These voice and throat symptoms his friends attributed to his having taken cold while working in a draught.

There were the signs of a rash on the body; but as he wore a flannel and usually perspired freely while at work, the cause of the eruption was uncertain.

His respirations were 30 per minute and his pulse 108. He had been at work during the forenoon of the preceding day, and had retired at 8 P.M., feeling quite well, except that he had some pain and stiffness in back. He complained of dizziness about 9 P.M., and an hour later, about 10 P.M., he arose from bed, tried to wind his watch with a table-knife, and next proceeded to cut it to pieces. As the night wore on his delirium and vertigo became more intense.

Restlessness, huskiness of voice, and thirst appeared; and all these symptoms gradually worse, up to the time I saw him, at 11 A.M. next day.

This case seemed clearly one of belladonna poisoning; but, as he had taken no medicine of any kind internally, I felt puzzled to account for the cause, until I at last discovered on his back what afterward proved to be a belladonna plaster.

He had had some pain in back during the preceding day, had rubbed his loins at about 4 P.M. with an irritating liniment which was in common use at the machine-shop, and at about 8 P.M. had applied a belladonna plaster on the recommendation of a neighboring druggist.

The plaster (five by eight inches in size) was carefully removed. Some spots of abraded skin were discovered underneath, which his wife assured me were not present when plaster was applied.

Small doses of opium were ordered at intervals of two hours.

Six hours later, when I again saw the patient, his condition was very much improved. He now recognized his friends about him and was able to give an intelligent account of how he felt. His delirium had vanished. Vertigo, restlessness, huskiness of voice, and dryness of throat were far less marked, and by the following morning all the apparent physiological effects of the drug, belladonna, had well nigh disappeared, except the dilatation of pupil.

The patient has since assured me that he had no recollection whatever of anything that had happened from the beginning of the active stage of delirium up to the time of the administration of the third dose of opium. The points of interest in this case that, to me, seemed to make it worthy of being reported, were as follows:

First.—The unusual cause, and the consequent liability of the medical attendant to overlook that cause; very few cases of poisoning from the use of the belladonna plaster, as far as I know, having been reported.

Second.—The rapid development of delirium, suggesting, possibly, a peculiar susceptibility of the patient to the action of the drug.

The case also suggests the advisability of cautioning patients to avoid applying such plasters over an abraded skin surface. It furnishes an instance of the delirium produced by drugs being sometimes confounded with the symptoms of insanity, and illustrates one of the dangers of counter-prescribing.

139 Lexington Avenue.

ELECTRICITY IN SUPERINVOLUTION AND SUBINVOLUTION OF THE UTERUS.

By A. D. ROCKWELL, M.D.,
NEW YORK.

Dr. Fordyce Barker, in some remarks made before the last meeting of the American Gynecological Society, on superinvolution of the uterus, stated that, in a small proportion of cases could be benefited by any method of treatment. In his opinion very little could be accomplished when the difficulty was associated with evidence of arrested or defective ovulation; while in those cases where benefit was derived, there was always evidence of active ovulation. He regarded as symptoms of the existence of ovulation associated with superinvolution—disturbance of the vascular or nervous system at or near the menstrual period, such as intense headache, flushing of the face and congestion of the eye, pelvic pain and sense of dragging, with nausea, vomiting, etc. In the following case, lately seen and treated, some of these symptoms were distinctly marked, and so far forth, are confirmatory of Dr. Barker's experience.

At stated periods there was severe headache, pelvic pains, and nausea. Associated with these symptoms, and far more persistent than any of them, was a condition of melancholia that became intensified during one interval preceding the effort at menstruation, and manifesting itself by an insuppressible aversion for persons and things that ordinarily excited in her no such feeling. Two years previously she had suffered from a difficult and dangerous labor, where it became necessary to dismember the child, and since that time the menses had not appeared, excepting on two or three occasions, when it was exceedingly scanty, and in other ways unnatural. Upon measurement, the uterus was found to be but about one and three-fourths of an inch in length. The patient was treated almost daily, for about three months, by internal applications of both faradism and galvanism, when a slight show appeared for the first time in eighteen months.

At the next menstruation, a few weeks subsequently, the flow was much more abundant.

I regret to say that after the first month I neglected to repeat the measurement, and since the rather abrupt discontinuance of treatment, no opportunity has presented itself.

The reappearance of normal menstruation would, however, seem to be sufficient evidence of the entire success of the efforts made.

In subinvolution of the uterus, my experience, though limited, has been somewhat greater than in superinvolution. Among several cases where undoubted amenorrhoea occurred, I have in mind one in particular, which Dr. T. G. Thomas saw with me, and pronounced to be one of subinvolution.
Excessive menstruation, with abundant leucorrhoea, together with other symptoms, attributed to the size and weight of the organ, were associated in this case. Occasional local applications wrought, within a few months, a very great change in the condition of things.

The menstruation, instead of being excessive and continuing for nearly a week, became almost scanty and with a duration of only twenty-four hours.

The leucorrhoea ceased to annoy her to any extent, and the leucorrhoea and other symptoms were observed to be dependent upon the enlarged uterus entirely disappeared.

The apparently paradoxical action of electricity, as illustrated in the treatment of superinvoluted and subinvoluted of the uterus, is not a new thing. We constantly find that it relieves both hyperesthesia and anesthesia. It is used successfully to excite torpid excretory processes, and also to retain fluid, as its action when too active. In the same way it may cause increase or it may cause diminution in the size of a part or organ.

Goitres, for example, are readily reduced in size, and sometimes entirely disappear under simple external galvanisation, and so with other forms of morbid growths. On the other hand, it is well known to all whose experience has been extended, that certain functions may be surprisingly developed by persistent local applications. It is perhaps not out of place to say here, as an illustration of this point, that the arms of the writer, having been much increased in size, and even strength, by the frequent action of a current of faradism on them through a series of years, and in the line of professional work, is an example of such a result. Regardless of results herewith given, the possibility of obtaining better results than heretofore in the opposite conditions of super- and subinvolution of the uterus is quite evident.

Progress of Medical Science.

Excision of the Shoulder-Joint.—Among the operative measures as regards the merits of which surgical opinion is undergoing change, resection of the shoulder-joint occupies a conspicuous place. Mr. William Stokes (British Medical Journal, November 10, 1883), from a careful consideration of the subject, is led to announce the following propositions: 1. The operation should be performed by the Ollier-Langenbeck method, avoiding, however, in pathological resections periosteal-capsular preservation. 2. The excision of bone should be as limited in amount as is compatible with the removal of disease. 3. Preservation of the periosteum is only indicated in traumatic resections, where there is much involvement of the atrophy of the humerus. 4. The use of splints is not indicated in the after-treatment of resection of the shoulder-joint. 5. Rapidity of union is strongly indicated after this operation, and can best be obtained by a rigid adherence to Listerian antiseptic practice. 6. Passive movements, gymnastic exercises, and massage should be commenced as soon as possible after the operation.

The station and position of the patient during the operation are methods for traumatic or pathological, supplicative or non-suppurative lesions, are eminently satisfactory and encouraging.

Iodoform in the Treatment of Ophthalmia.—Iodoform appears to be finding favor with German oculists in the treatment of certain ophthalmic affections, and notably catarhal conjunctivitis, purulent conjunctivitis, and granular lida. Encouraged by these successes, M. St. Martin, of Paris, has adopted the treatment in palpebral granulations, with consecutive vascular pannus, cicatrices of the cornea, and keratitis, and is well satisfied with the result. The effect of the agent in the last-named affection was little short of marvelous. The iodoform was employed with vaseline, equal parts of each, and introduced into the cul-de-sac of the eye affected. The eyelids were then closed and covered with a piece of fine linen and cotton wool, the whole maintained by a flannel bandage, and left on until the following day. In a case of double pannus of long standing, six weeks sufficed for a cure, all trace of the cicatrix disappeared at the end of three months. That form of keratitis known as keratitis en Candelette, yielded in a rapid manner to the treatment. Out of twenty-one patients, eighteen got completely and rapidly well without relapse, the three others recovered less promptly. In a case of diffused keratitis the pomade seemed to have no effect.

The Action of Salicylate of Soda on the Uterus.—Sabatowski has shown that salicylate of soda has a markedly good effect in calming the pains accompanying the so-called arthritic dysmenorrhoea, and in his Thèse he insisted on the menorrhagic action of this drug, which was previously mentioned by Bucquoi. M. Balette (Thèse de Paris, 1853) has published several cases confirmatory of this action. It produces visceral concretions, which may cause hemorrhage; it is at this point that the uterine hemorrhage appears. Hence it may excite and bring on the menstrual flow. Whether or not the drug is an abortifacient still remains to be seen, though experiments on guinea-pigs have completely negativised this idea. It is probable, however, that in regard to its oxytocic properties it has been almost as much malignised as susbacte of quinine.

Treatment of locomotor Ataxia by Cutaneous Faradisation.—Dr. C. Engelskjøn reports at length in the Nordisk Magasin for Laegvitsienstaben, No. 3, 1883, the histories of two cases of tabes dorsalis treated by him by cutaneous faradisation. The first case was that of a lady, thirty-nine years of age, of nervous temperament, and presenting a family history of various nervous diseases. Her ataxia dated back about three years, the first manifestations being a difficulty in ascending the stairs, and a sensation as if she would fall over backward. About six months later she was unable to stand without tottering when the eyes were closed, and began to complain of pains in the limbs. The most varied plans of treatment were tried without effect, and her condition continued to grow worse. It then that a trisuras made a strong application of the skin of the forearm. The effect was almost instantaneous. The pains, which had been excruciating, were relieved at once, and although they soon returned, were always driven away by a reaplication of the current. This treatment was continued twice a day for several months, at the end of which time every trace of ataxia had disappeared. The subject was then sent away. It is difficult to say in this case whether the symptoms were not hysterical, but the author thought that they were not. The second patient was a man, forty-seven years of age, who gave a history of syphilis twenty years previously, and who had had symptoms of tabes for seventeen years. Electricity, applied in the same manner as in the former case, was successful in eliminating the pains, though at the time the report was made the treatment was of too short duration to allow of any marked improvement being noticed in the other symptoms. And the author had but little hope that any permanent result would be obtained owing to the length of time that the disease had existed. While he was pursuing these investigations Dr. Römer published a paper in the Medizinische Centralblatt, describing the same method. Dr. Engelskjøn found that the same effect was produced by the galvanic current applied in the same way, and further, that it was due solely to peripheral nerve irritation, as the same, or even more striking, results, as regards the quieting of the laning pains, followed the application of a mustard bandage. He ever, however, to therapeutic value in those cases of locomotor ataxia, the first symptoms of which are referable to atrophy of the optic nerve.
ON THE VALUE OF METALLO-THERAPY.

It is now about four years since the subject of metallo-therapy was brought prominently before the scientific world by second report of the Committee of the Société de Biologie. At that time we discussed the matter editorially, and expressed the opinion that metallo-therapy was not a thing of very great importance practically, and that its scientific legs were still very weak—outside of Paris. Since then the subject has been studied with great industry, though still chiefly in Paris. Quite recently a writer in the Archives of Medicine, Dr. Grace Peckham, has presented its claims to the profession in this country. The writer begins with a quotation from Charcot: "Metallo-therapy is no more denied. It is a question solved; the facts have been methodically established and now remain an acquisition to science."

An account is then given of the clinical facts observed concerning metallo-therapy and the theories offered to explain them.

These phenomena, produced by the application of metal discs, and which consist chiefly in changes of sensation, are quite well known to the profession. The theories offered to explain them, however, have been multiplying, and now amount to four, viz.: the theory of expectant attention, the electrical theory, the theory of mechanical irritation, and Schiff’s molecular theory. While none of these appear to satisfy our critic’s mind the theories of expectant attention and the electrical theory are positively rejected as insufficient.

Dr. Peckham then relates a number of cases of his own in which metals have been used with success, and describes the technique of this branch of therapeutics. The cases related are those chiefly of paraesthesia, anesthesia, or hyperesthesia, and pain, in women. The application of metal plaques in all instances produced relief or cure.

The fact that the application of various metal plaques to the anesthetic limbs of hysterical women will produce changes in the condition of the sensory mechanism is one about which there can be no question. It happens, however, that almost any mechanical, electrical, or chemical irritant will produce the same result. Thus, bits of wood, blisters, weak electrical currents, magnets, even tying a handkerchief around the affected part, will produce the same results. This may occur also even when the anesthesia is of organic origin. No theory, therefore, has yet been advanced which is so satisfactory, on the whole, as the one which supposes that the phenomena are entirely mental, and dependent upon attention, expectant or non-expectant. Despite the large amount of careful work, therefore, expended upon the subject, we must still consider that the scientific and practical outcome is small.

Because metallo-therapy is still considered by most of the scientific world a part of mental therapeutics, it does not follow that it is altogether useless or without practical value. Certainly some very good results are obtained at times, and we can conscientiously urge American physicians to test it more extensively than has yet been done.

The method of using metals is briefly as follows: The physician must have a considerable number of discs of iron, copper, zinc, gold, silver, tin, and platinum. The personal sensibility of the patient must then be tested, in order to find out to which one he is the most sensitive. A disk is applied to the affected part and, if it is the right one, it will, we are told, generally cause a sense of warmth, burning, or pricking within half an hour or an hour. Five to twelve disks can then be applied and left on until relief is felt. Burq uses a still greater number, and even "drapes" his patient with the proper metal. Dr. Burq also considers that the same metal should be given internally, either in the form of a powder of the pure metal or a solution of its salt. Burq and Charcot give the following as the order in which to try metals: Iron, zinc, copper, gold, silver, tin, and platinum. Vigoureux says that among one hundred persons, seventy are affected by iron, while thirty are affected by the remaining metals. It remains to be seen in what order the insensible and hard-headed American responds.

THE SIMS MEMORIAL FUND.

The good work inaugurated and under the direction of the Central Committee goes forward enthusiastically. Before the formal appeal was made several subscriptions of one hundred dollars each had been offered, and others have arrived since, which remove any doubt as to whether or not the medical profession is ready and willing to pay homage to the name of him who erected for himself a monument more enduring than either bronze or marble.

We earnestly hope that no one will hesitate to contribute because he is unable to place to his credit in this fund a large sum of money, as subscriptions of one dollar and upward will be gladly welcomed.

A NEW MEDICAL SOCIETY.

The physicians in this city who have found themselves in the minority on the subject of a restrictive code have organized a new medical society, which is called "The New York County Medical Association." The first formal meeting was held last Monday evening, February 14th, when Dr. Detmold presided. In an address of welcome, that gentleman stated that the main object of the new society was to secure a representation for this State in the American Medical Association. To this end attempts would be made to organize other new county societies and to form a second State Society.

It was a shrewd movement on the part of the President to turn the issue in this direction, for no one can
and fault because many desire to be recognized by the American Medical Association.

The only question which arises in candid minds is, whether it was wise to take a step which necessarily increases the discord and accentuates the difficulties among the members of the profession in this State. If patience had been exercised and some attempt to work harmoniously had been made, the object desired, of representation in the National Association, could undoubtedly have been gained without thus making an open rupture in the profession. As it is now, at the very utmost, they can only secure the partial representation of a profession crippled and divided by the new movement. The satisfaction which will be felt cannot be great to generous minds.

We fear that the statement regarding the objects of the association is hardly an ingenious one, and that its existence is more the expression of ill-temper and disappointment than of the efforts of men earnestly desiring the highest interests of the profession.

THE NEW HOSPITAL OF THE POST-GRADUATE MEDICAL SCHOOL.

The success of the Post-Graduate Medical School has been such as to compel the faculty to obtain larger accommodations than they have heretofore had. The school has been fortunate enough to secure a building admirably adapted for clinical instruction and for the purposes of a hospital. It is situated at East Twentieth Street, and is a large, well-built four-story structure with over ninety feet front. It contains rooms sufficient for the accommodation of about one hundred patients, besides a well-lighted lecture and operating room, and large rooms for dispensary work. We are informed that the Faculty will use the basement, the first floor and part of the second, for out-patients and for purposes of clinical instruction, laboratory work, etc. The remainder of the building will be devoted to in-patients. In the rear of the hospital there will be a dead-house and a room for experimental work.

The Post-Graduate Medical School will, with this new building and its appurtenances, be most admirably equipped in every way for the purposes of practical, clinical instruction.

The medical profession is to be congratulated that the opportunities for obtaining this kind of instruction have been so very much increased in the past year, chiefly through the agency of the postgraduate schools. It is a satisfaction to learn that the New York school, which led the movement in this city, has met with such indubitable success, and has made its clinics so rich and fruitful in every department of medicine.

A few years ago there was some excuse for a doctor graduating and going into practice without ever having seen a case, except perhaps from the back seat of a large amphitheatre. Now, with our well-supplied clinical schools, it is unpardonable that such a thing should happen.

SECOND-CLASS STEAMSHIP DOCTORS.

It is stated on the authority of the Medical and Surgical Reporter that the doctors on the Red Star Line, running between Antwerp and New York and Philadelphia, have been obliged by the Company to live second-class. Instead of dining with the captain and cabin passengers, they have to mess with the steward and submit to the accompanying social indignities. The Red Star Line is owned by Belgians, but it is officered, we are told, chiefly by Americans. The Red Star doctors have naturally protested against the treatment which they have received, but without avail, and some have in consequence resigned. The medical profession is urged to take up the cause of these second-class doctors and urge the Company to restore them to their cabins.

If protests would produce the slightest effect upon the Company, we might be disposed to indulge in them. They would, however, be, as medical protests have almost always been, of no avail whatever. The ship-surgeons must attend to this matter themselves. And they can do it. If they are really educated men and gentlemen they will not consent to be meantly lorded over by a few autocratic shipowners. If they are not gentlemen, why let them mess with the steward. They must not ask the profession to push them in with a better class, simply because they are doctors of medicine. It is no disgrace to dine at the second table. It is only a humiliation to feel that ignorant "Sam'ls of Posen" should be allowed to sit higher than members of a learned profession.

The ship-surgeons, however, we repeat, have the matter in their own hands. They owe it to the profession and themselves not to allow themselves to be insulted. If they do not resign, but sit cringly with the servants and plaintively ask to be pulled up higher, they deserve nothing but what they get. If they resign, then whoever is so small-spirited as to creep into the vacancies is doubly worthy of professional contempt and ostracism.

THE PRESCRIPTION-PAD AND THE PESTLE IN CINCINNATI.

The physicians and pharmacists of Cincinnati have been having discussions and conferences, which have resulted in the following pretty bit of nonsense:

"First.—Pharmacists shall not prescribe medicines for diseases.

"Second.—Pharmacists shall not too frequently fill prescriptions which might lead to disease or vicious habits.

"Third.—Pharmacists shall only supply medicines on prescriptions, or where the complaint is stated by a customer to be one dangerous to life.

"Fourth.—The right to refill prescriptions, when presented by the person to whom they were issued by the physician, is acknowledged.

"Fifth.—Physicians should not dispense medicines, except in cases of emergency, nor prescribe proprietary, secret, or copyright medicines.

"Sixth.—The prescriptions, when in the hands of the pharmacist and filled, shall be the latter's property, as they may be necessary for protection.

"Seventh.—The use of prescription blanks by physicians, with the address of any individual pharmacist on them, is liable to misconstruction, and shall be discontinued.

"Eighth.—The evils arising from the wholesale use of
patent medicines are recognized, and their use discon-
tenanced.

"Ninth.—A Board of Arbitration, consisting of five
physicians and five druggists, shall be appointed, who
shall subscribe to these rules. This Board shall hear all
complaints against any subscriber to these rules for their
violation, and shall decide disputes."

There is hardly a section of the above which does not
announce something that is impracticable, meaningless,
or (as in section six) in direct opposition to judicial de-
cision. Druggists always prescribe a little. Doctors
certainly can and will dispense medicines if they find it
better for their patients. In fact, the poor patient, who
is really the main thing after all, seems to be quite for-
gotten in the above ridiculous production. When doc-
tor and druggist feel obliged to meet together in order
to formulate the rules for dividing the spoils, things have
come to a very bad pass.

THE COLLEGE OF MIDWIFERY.

In our last number we called attention to the disrepu-
table announcement which this institution had made, and
also published the confidential card that accompanied the
Circular-letter. We also directed attention to the fact
that this extraordinary action of the College tended to
do an injury to the Censors, Drs. Mundé and Dawson.
We have since received a letter from those gentlemen,
in which they make it known that they had resigned
unconditionally on the 8th of January, immediately after
receiving the objectionable proposition. (See p. 80.)

These gentlemen thus have, with credit to themselves,
severed completely their connection with the organiza-
tion. But are the resignations of Drs. O'Reilly and
Alsdorf equally unconditional? If so, why do they still
maintain their connection with the Infirmary and Dispen-
sary? Perhaps Dr. O'Reilly or Dr. Alsdorf will inform
the profession concerning the exact origin of the card
offering commissions on cases or students sent to either
the College or the Infirmary.

THE RISK OF PRESCRIBING STIMULANTS IN KANSAS.

The laws of Kansas do not allow the prescription of
liquors by physicians except under circumstances of ex-
trme need, and the physician has to take the risk of a
jury's deciding against him on this point.

A case of this kind came before one of the courts of
that State not long since under rather amusing circum-
cstances. A person who was fond of beer went to a phy-
sician claiming to be sick, and after an examination a
prescription for two bottles of beer was written out.
The patient obtained the beer, returned to the office of
the physician, and then upon the latter's invitation the
two went to a neighboring restaurant, regaled themselves
upon some oysters and the two bottles of beer, each
drinking one. After this they attended a party together,
remained a while, and then returned to the physician's
office, and after an hour or two of conversation the pa-
tient went home.

These facts were brought out before the jury together
with the testimony of the physician, that he had acted in
good faith and believed the beer to be the proper rem-
edy. Under these circumstances the question was sub-
mitted to the jury; and it is not a matter of great sur-
prise that they found the physician guilty of a violation
of the statute.

THE HOSPITAL COLLECTIONS.

The funds obtained through the Hospital Saturday and
Sunday collections are not, at date of writing, entirely in,
but sufficiently full reports are published to give an idea
of what this year's work has accomplished. Up to January
15th there had been received $28,471.49 from all sources.

Unless some unexpected additions are received, this
sum, though considerable, is disappointing, for it shows
that there has been a steady decline in the receipts from
these collections from $44,000 in 1879; $33,000 in 1882,
to the present amount; and this has occurred despite the
most earnest efforts of the Hospital Fund Committee.

The total amount given by the churches this year, ac-
cording to the published figures, is not far from $14,000,
and is considerably less than the amount ($18,000) given
last year.

As before, the Episcopalian churches take the lead,
giving more than all the others together, viz.: about
$8,000. The Presbyterian churches have given a little
more than they did last year. The Methodist churches
last year contributed a paltry $204; this year the sum
is between one and two thousand dollars.

The Baptists ought to be, of all denominations, most
ashamed of themselves. Though numerically one of the
most prosperous sects, their total contributions to the
hospitals are less than $200, so far as the figures now
published show.

The synagogues did not give very much this year.
Full reports as to the trade and private collections will
be given later.

News of the Week.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.—The
titles of papers, printed in the order of their reception,
to be placed before the Business Committee of the Medici-
sal Society of the State of New York, at the opening of
the seventy-eighth annual meeting, February 5, 1884, are
as follows:

1. Malignant Lymph-Adenoma, with Cases, Dr. L. S.
    Philcher, Brooklyn; 2, Dysmenorrhoia, its Treatment
    by Dilatation, Dr. W. W. Potter, Buffalo; 3, Operation
    for Closure of the Hard and Soft Palate, with Results,
    Dr. A. Vanderveer, Albany; 4, Value of Electricity in Diag-
    nosis, Dr. L. E. Felton, Potsdam; 5, The Treatment of
    Suppurative Otitis in Children, Dr. S. Sexton, New York
    City; 6, A Case of Sympathetic Serous Iritis, with Re-
    marks, Dr. D. Webster, New York City; 7, Strangulated
    Hernia, with Reports of Five Cases Treated by Opera-
    tion, Dr. J. Chapman, Medina; 8, Two Unusual Cases
    in Obstetrical Practice, Dr. W. C. Wey, Elmira; 9, A
    New Method of Partial Extirpation of the Cancerous
    Uterus, Dr. E. Van de Warker, Syracuse; 10, Two Cases
    of Poisoning by Tansy, Dr. W. Woodward, Big Flats;
    11, Haematuria; 12, Two Cases of Extra-Uterine Pre-
    gnancy; 13, Two Cases of Rupture of the Heart, Dr. T.
    H. Squire, Elmira; 14, Management of Face Presenta-
    tion, Dr. E. L. Partridge, New York City; 15, Morbid
Compulsory Examination of a Female Plaintiff in an Accident Case.—A case in this State was recently commented on where the court refused to order a compulsory examination of a female plaintiff in an accident case, to see whether she had not some other ailment besides the hurt caused by the accident.

A case involving the right of the court to order a medical examination is presented in one of the Western States, but under circumstances entirely different from that mentioned above. In this latter case there was a permanent injury to the eyes, and no medical examination had been had at any time, and the court held that it had the right to order such examination.

Active Medical Fathers.—We are enabled to add to our honored list of old physicians, who are still in practice, the following gentlemen: Wm. N. Blakeman, aged seventy-eight; Joel Foster, aged eighty-one; James Knight, aged seventy-three; A. S. Purdy, aged seventy-five; S. A. Purdy, aged seventy-two; G. A. Sabine, aged seventy-four. Let the younger men take courage, and "learn to labor and to wait."

The Proposed Post-Graduate School in Baltimore has been organized, and goes by the name of the Baltimore Polyclinic. We observe that it spells its name correctly, i.e., with an "I."

Glanders has appeared again in Illinois.

A Neurological Society is to be organized in Philadelphia.

The New York Pathological Society.—The proceedings of this society have been translated into French and appear in the Journal de Medicine de Paris.

A Medical Society for British Medical Officers has been organized at Woolwich.

A Physician in Disgrace.—Dr. G. H. Greeley, the Syracuse physician who has been arrested for forgery, was not a man of any standing in the regular profession, as evidenced by the Green Book.

The New York Post-Graduate Medical School will remove to its new quarters No. 226 East Twentieth Street, on or about February 1st. The new building has all the facilities necessary for hospital purposes, and it is the intention of the Faculty to intimately combine bedside practice with the ordinary teaching of the school. Sixteen thousand patients were treated under the auspices of the school during the year ending November 1, 1883, and one hundred and forty physicians matriculated. About ninety physicians have matriculated since September 1, 1883.

Dr. William Oliver Moore has been appointed Professor of Eye and Ear Diseases in the New York Post-Graduate Medical School.

The Suit Against Dr. David Webster, brought against him as President of the New York County Medical Society by a person whom he had caused to be arrested for practising without a license, came on this week. The judge instructed the jury to bring in a verdict for the defendant, which was done.

The Collections for the Brooklyn Hospitals amounted to $4,604.50, which is $250 more than was received last year.
A RAID ON QUACKS IN CHICAGO.—Under the direction of the State Board of Health of Illinois, the Chicago police opened war against the "specialists" and quack doctors last week. A number of detectives with a patrol wagon raided the office of a "Doctor" J. R. Williams, and captured not only the proprietor but also two wagon loads of obscene pamphlets and cheap books. These were all burned in the furnace at one of the police stations, where the "doctor," who was unable to procure bail, was locked up. The warrant sworn out by the detectives charges Williams with circulating obscene literature. In addition to his stock the officers found a lot of obscene publications belonging to Lucas R. Williams, better known as "Dr. Lucas," a brother of the arrested specialist.

A GOLD MEDAL has been awarded to Mr. Ayerst H. Hooker, an Englishman, residing in Egypt, for his heroic efforts in attending the sick and fighting disease during last summer's cholera epidemic.

AURUM VEGETABLE is the attractive euphemism for "pipitazahuate," a Mexican drug much esteemed for its cathartic properties. According to Carl Moir there are many varieties of the plant (botanical name Persica) in America.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.—The annual meeting of this Society will be held at Philadelphia on May 14th, 15th, and 16th, 1884, in the Assembly Room of the Union League, Broad and Walnut Streets. The President's reception and the entertainment by the Philadelphia County Medical Society will be held on the evening of May 14th, at the Pennsylvania Academy of the Fine Arts, Broad and Arch Streets. The by-laws require the programme of the meeting to be printed and distributed at least one month before the date of the meeting; and no voluntary paper is allowed to occupy more than twenty minutes in its reading. Notice is hereby given that all those who wish to present papers should send the full title and a short abstract of the same to the Committee on Arrangements on or before March 1, 1884, in order that a varied and attractive programme may be prepared. No paper will be selected for a position upon the programme of the meeting unless an abstract has previously been seen by the committee. By order of the committee, JOHN B. ROBERTS, Chairman, 1118 Arch Street, Philadelphia.

THE PRIZES OF THE ACADEMIE DE MEDECINE.—The recipients of these prizes and the amounts bestowed are as follows: Académie Prize (1,000 fr.), "Generalized Arterial Atheroma, and its Influence upon Nutrition," awarded to Dr. Hipolyte Martin. Portal Prize (2,000 fr.), "The Lymphatic System from a Pathological Point of View," to Dr. A. Poulet. Bernard de Cuvier Prize (2,000 fr.), "The Causes of Locomotor Ataxia," to M.M. L. Landouzy and G. Ballet. Capron Prize (2,000 fr.), "The Lachia in Normal and Pathological States," to M. Dr. Eustache, of Lille. Barbier Prize (4,000 fr.), to be awarded for the discovery of cures for diseases heretofore thought incurable; such as epilepsy, cancer, etc., awarded to Dr. Willems, of Belgium, for his works upon inoculation of pleuro-pneumonia. Godard Prize (1,500 fr.), divided between M. Leloir, of Paris, and M.M. Feliz and Ritter, of Nancy. Despotres Prize (2,000 fr.), not awarded. The money, however, was given as an "encouragement" to three competitors. Buignet Prize (1,500 fr.), not awarded. Orfila Prize (4,000 fr.), not awarded. Itrid Prize (3,000 fr.). This prize was divided between Dr. Sanné, for his work on diphtheria, and Dr. Paul Latteux, for his manual of microscopical technique. Fabret Prize (1,500 fr.), "Vertigo with Delirium," to Dr. Paul Garnier. Saint-Sager Prize, not awarded. Saint-Paul Prize (25,000 fr.), offered for a specific against diphtheria. Five hundred francs were given as an encouragement to Dr. Letour for his essay. Infantile Hygiene Prize (1,000 fr.), divided between three competitors. A large number of gold, silver, and bronze medals was also distributed.

NEW YORK OPHTHALMOLICAL SOCIETY.—At the nineteenth annual meeting held on Monday evening, January 14th, the following officers were elected for the ensuing year: President—Dr. David Webster; Vice-President—Dr. C. I. Kipp (of Newark, N. J.); Secretary and Treasurer—Dr. James L. Minor.

AMERICAN PORK vs. GERMAN AND FRENCH WINES.—Retaliatory measures have been proposed to be carried out by the enactment of a law by Congress which would so vitally affect the wine market as to drive out the German and French products of the vine. A boom in discrimination in quality can be raised with equal ease, and would be more justifiable than that which has excluded from their markets one of our staple products. The old saying, "You kick my dog, I'll kick your cat," holds a principle which may be applied, wisely or otherwise, in more extensive fields than the domestic circle.

GUARDING AGAINST THE INGRESS OF CONTAGIOUS DISEASES.—The health officer of this port, Dr. William M. Smith, in an open letter to the New York Times says, it has come to his knowledge that holders of rags in Egypt propose to ship them to the United States, and therefore he notifies all persons interested that evidence of the thorough disinfection of such rags will be required before they will be permitted to pass this quarantine. He further informs all interested parties that he is in a position to be notified of all shipments from Egyptian ports, direct or otherwise, of this article of commerce.

YELLOW FEVER IN THE CITY.—A tobacco merchant of this city returned from a visit to Cuba on January 7th. Next day he was taken ill, and the disease was pronounced to be yellow fever. No quarantine was attempted. The patient died on the 12th inst.

THE BILL TO ESTABLISH A MEDICAL FACULTY OF THE University of the State of New York was introduced into the Assembly on January 14th, by Mr. Howe, of New York.

AMERICAN PORK IN GERMANY.—An interview with Professor Virchow was announced by cable to the Herald, January 14th, in which it is stated that this eminent pathologist condemns as utterly illogical, unnecessary, and unjustifiable from sanitary reasons, the present prohibition against American pork in Germany and France. He further says that no cases of trichinae in American pork have been proved to exist in Germany for ten years.
CONSULAR HEALTH NOTES.—The United States Consul at Callao states that the yellow fever made its appearance on board the mail steamer Lima while en route from Panama to Callao, and that three deaths occurred on board. No other cases appeared after her arrival, but she was put in close quarantine, and every precaution taken to prevent the disease reaching the city. He adds that on account of the advent of hot weather much anxiety is felt.

The United States Consul at Buenos Ayres reports the landing at that place of two cases of yellow fever from a French steamer which touched at Rio, and that Montevideo has established a ten days' quarantine against Buenos Ayres for that reason, although the latter place has a quarantine of three days against all Brazilian ports.

The report of the total number of cases and deaths at Pensacola Navy Yard and Reservation during the yellow fever epidemic of last year is as follows: Pensacola Navy Yard, 15 cases, 6 deaths; Woolsey and Warrenton, 152 cases, 27 deaths; total, 167 cases, 33 deaths.

The report of Sanitary Inspector Burgess, of the Marine Hospital Service, shows that there were 578 deaths from all causes at Havana, Cuba, during the year just closed, of which 53 were from yellow fever, 11 typhoid fever, 13 malarial fever, 4 diphtheria, 4 croup, and 1 from glanders. Forty-three of the yellow fever deaths were among citizens and the merchant marine, and the remainder among the army and navy. As compared with last year there were 535 deaths from all causes, and but 24 from yellow fever. During the week ending January 4, 1884, there were 7 fatal cases of yellow fever, against 4 for the same period last year.

The United States Consul at the island of Malta states that quarantine on all arrivals from Egypt has been established, as follows: Ten days' quarantine in case of a healthy voyage exceeding ten days; fifteen days for a voyage less than ten days; twenty days' strict quarantine in cases of the least suspicion of disease on board, or of unsatisfactory hygienic condition of vessel, whatever be the duration of the voyage. The sfratto against passengers from Egypt arriving in healthy vessels is abolished.

BILLS BEFORE CONGRESS.—The following bills have been introduced in Congress, which are of interest to our readers: Senate Bill 982, introduced by Senator Miller, of New York, for the maintenance and support of the Marine Hospital Service, read twice by title and referred to the Committee on Commerce. House Bill 2,697, introduced by Mr. Randall, of Pennsylvania, to prepare and publish a National Pharmacopoeia for the United States, which was read a first and second time, referred to the Committee on Ways and Means, and ordered to be printed. House Bill 2,785, introduced by Mr. Young, of Tennessee, to amend an act entitled "An act to prevent the introduction of infectious and contagious diseases in the United States, and to establish a National Board of Health," which was read a first and second time, referred to the Committee on the Public Health, and ordered to be printed.

INTERNATIONAL MEDICAL CONGRESS.—M. de Bille, Danish Minister to the United States, has transmitted to the Secretary of State a letter of invitation from the General Organizing Committee of the International Medical Congress, and says: "I am officially informed by my Government that the Eighth International Congress for Medical Science will meet at Copenhagen in the days from the 10th to the 16th of August, 1884. The different States having generally been represented, at the preceding meetings of this Congress by official delegates, his Danish Majesty's Government entertains the hope that this may also be the case at the impending Congress. Conforming to the wish expressed by the Board of Organization, I am instructed to assure the Government of the United States that the Danish Government would highly appreciate the fact of its being officially represented at the Congress, and to invite you to inform me, in good time, of the names of the delegates to whom may be entrusted this distinguished mission."

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The annual meeting of the College of Physicians of Philadelphia was held on January 2d, when the following officers were elected: President—Dr. Samuel Lewis; Vice-President—Dr. J. M. DaCosta; Secretary—Dr. Richard A. Cleeman; Treasurer—Dr. Charles S. Wurtz.

THE PHILADELPHIA COUNTY MEDICAL SOCIETY held its annual meeting on January 2d, and elected the following members: President—Dr. Wm. M. Welch; Vice-Presidents—Dr. Wm. S. Forbes and S. R. Knight; Recording Secretary—Dr. Henry Leffman; Corresponding Secretary—Dr. M. S. French; Treasurer—Dr. L. K. Baldwin; Censor—Dr. H. St. Clair Ash. Two female physicians who applied for membership were rejected by a two-thirds vote.

THE PALACE OF THE EX-EMPRESS EUGENIE AT MARSEILLES, which she was obliged to give back to the city, has been turned into a medical school for the training of army medical officers and others. Four hundred thousand dollars has been voted for its use by the municipal government. Drs. D'Arsonval, Malassez, Masé, and others are to be attached to the school.

NEW JOURNALS.—The Iowa State Medical Reporter is the title of a new monthly medical journal, of excellent appearance, published at Des Moines, and edited by Dr. F. E. Cruttenden, and others.

The Texas Courier-Record of Medicine is the name of a new and enterprising monthly, edited by Drs. F. E. Daniel and W. B. Brooks, and published at Fort Worth, Texas. It announces that Dr. John A. Wyeth is a member of the Faculty of the Philadelphia Polyclinic and College for Graduates in Medicine. Such is fame.

TROUBLE IN A ST. LOUIS MEDICAL COLLEGE.—For some time there has been trouble brewing in the St. Louis College of Physicians and Surgeons, between the Board of Trustees and Dean on the one hand, and the Faculty and Students on the other. According to statements in the daily press, the college was started five years ago under the auspices of prominent Democratic politicians, and Col. James O. Broadhead, now member of Congress from St. Louis, was elected President, and William Hyde, editor of the Republican, Vice-President, while almost all the other Directors are shining lights in the local Democratic fold. A telegram to the New York
Times says: "The attempt to combine pathology and politics has been unsuccessful from the beginning, and while the Dean of the Faculty, Dr. Bauer, and Dr. Hazard, a medical member of the Executive Committee, have drawn their salaries regularly, the other professors have been put off from time to time with unwritten promises to pay. This, together with a lordly way the Directors had of disregarding any request made by the Faculty or students, has led to open revolt. On January 14th, eight of the Professors and all the students struck, and the Faculty now consists of three doctors and five students, whom they have persuaded to return to their studies. The college is burdened with a debt of $7,000, and unless some compromise is reached soon the institution will go under. The trouble is aggravated by the fact that both the President and Vice-President of the college were at the time of the revolt in Washington."

New Marine Hospital at Baltimore.—The commissioner appointed to select a site for the proposed Marine Hospital of Baltimore has secured six acres on Remington Avenue, in the northwestern part of the city, at a cost of $20,000, leaving $80,000 of the appropriation for buildings. The site is considered a very desirable one. It is expected that work will be commenced on the buildings as soon as spring opens.

The Free Hospital for Women, Boston, Mass., has recently received a gift of $35,000 from the wife of Lieutenant-Governor Oliver Ames.

Longevity of English Doctors.—The Lancet publishes a list of thirty-two English medical men who died during the past year, and who all attained extreme old age. Seven were over ninety years of age, and fourteen had passed their eighty-sixth birth-day.

Governor Walker, of Connecticut, in his annual message to the General Assembly, submitted on the 9th inst., calls attention to the fact that the Insane Asylum at Middletown, with its annex and cottages, is overtasked. With provision for 775 patients, the average number the past year was 854. Another building, to accommodate 250 patients, it is suggested, would meet the demand for ten years.

The Annual Meeting of the National Association for the Protection of the Insane and the Prevention of Insanity will be held in Philadelphia on January 22d.

Why Should the Spirit of Mortal be Proud?—This familiar commonplace, with its rhythmical sequelae, has been printed by a poetically inclined contemporary, The Southern Clinic. The esteemed editor endorses it as very beautiful and new. He is right in only the first particular. The poem was written by William Knox, in the early part of this century.

Scientific Enterprise.—Dr. Airing, late assistant to Professor Neisser, of Breslau, has been sent to Honolulu, in order to study the pathology of leprosy, and especially to investigate the question of the rôle played by the bacillus of leprosy in causing the disease.

A Crematory in New York.—The report is abroad again that a company has been organized for the purpose of building a crematory in or near this city.

A Medical Law for Ohio.—An agitation has begun in Ohio for the passage of a law appointing a State Board of Medical Examiners. The Central Ohio Medical Society, at its meeting in December last, earnestly urged this measure, which is being advocated by some of the medical journals, among them the Columbus Medical Journal. We trust that the movement will be successful, and that advantage will be taken of the experience of other States when the bill is framed. This has not always been done.

THE SIMS MEMORIAL FUND.

To the Medical Profession and Others throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting testimonial than obituaries and eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations, and such as have had the direct advantage of his personal skill are among the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulse to the study of gynecological surgery in America.

It is believed that the medical profession everywhere, the vast number of women who owe their relief from suffering directly to him, and those who realize the benefits he first made possible, will gladly unite thus to honor the man through whose original and inventive genius such blessings have been conferred upon humanity.

At the suggestion of many friends, therefore, the subjoined committee has been organized, and it is proposed that a suitable monument be erected to his memory in the city of New York.

To this end the active co-operation of the medical profession and the many other friends of Dr. Sims throughout the world is respectfully solicited. Contributions of one dollar and upward may be forwarded to the journal which has been constituted the treasury of this fund—The Medical Record, New York.

EPITHELIOMA OF THE PENIS—ENDARTERITIS OBLITERANS.

DR. PEABODY presented a specimen of epithelioma of the penis, and the chief point of interest was the existence, in the tissue of the epithelioma, of endarteritis obliterans, a condition which he had observed in three specimens of epithelioma. The specimen was removed from a man seventy years of age, who one year ago first noticed a small pimple on the left side and lower segment of the foreskin, and about three months ago it ulcerated and developed the ordinary gross appearance of well-marked epithelioma. Dr. Peabody presented microscopic sections which showed endarteritis obliterans distinctly, and remarked that he had found the lesion in a number of undoubted non-syphilitic cases. The lesion consisted in fully formed connective tissue growing from the intima of the blood-vessel, while the wall of the vessel seems to be in all respects normal.

DR. AMIDON said he saw this lesion in 1878 and 1879, in the New York Hospital, in a case of sarcoma of the humerus, but at that time he did not recognize its true character. One of the femoral arteries also was obliterated by the same growth.

ABSCESSES (?) OF THE KIDNEY.

DR. BEVERLEY ROBINSON presented the kidneys removed from the body of a woman, who gave the following history, according to the notes of DR. G. C. WEISS, House Physician, Second Medical Division, Charity Hospital: Bridget M., twenty-one years of age, single, born in Ireland, and a diabetic, was admitted waiting ward August 31, 1883. About three months advanced in pregnancy, and somewhat emaciated. She complained of incontinence and painful micturition. A few days subsequent to her admission the patient began to have irregular sweatings and chills with obstinate vomiting, and she lost flesh rapidly. Her urine contained a large quantity of pus.

October 21st.—The patient weighs about eighty pounds. Vomiting has persisted despite all remedies administered for its control. There is pain on pressure over the region of the kidneys. The urine contains pus in large quantity and the patient is jaundiced.

October 24th.—The patient had a miscarriage and lost about two ounces of blood. The placenta was delivered at the end of about forty minutes by manual assistance and expression. In the evening of the same day the patient seemed to be doing well, considering her general condition.

October 25th.—The patient vomited once during the night. Died from exhaustion at 8.30 A.M.

The autopsy revealed order of the lungs, normal heart, a liver weighing six and seven-eighths pounds, congested and fatty (?), kidneys weighing nine ounces each, with slightly adherent capsule, and surface studded with miliary abscesses. Section of the kidneys also showed abscesses varying in size from that of a millet seed to a silver three-cent piece. The pelvic were filled with pus. The uterus was well contracted, and neither shreds of membranes nor portions of placenta remained. The bladder was normal.

The character of the abscesses was obscure, and Dr. Robinson asked that the specimen be referred to the Committee on Microscopy. It was so referred.

DR. PEABODY thought that, in their present condition, the mililiary nodules on the surface of the kidney presented the appearance of tubercles rather than abscesses.

DR. ROBINSON also presented a specimen of PERFORATION OF THE LUNG IN PHLEBITIS FULMONALIS, followed by hydro-pneumothorax. It was accompanied by the following history, furnished by DR. SAMUEL T. KING, Assistant Senior Physician at St. Luke's Hospital:

Asmus S., twenty-four years of age, single, a German, and a paper-hanger, was admitted to the hospital October 6, 1885. He gave the ordinary history of phthisis, which continued until December 15th, when the patient died at 3.45 A.M.
The autops}y was made by Dr. F. Ferguson. Diaphragm on right side was at seventh rib, on left side at fifth rib. Thorax: On section of right thoracic wall gas escapes from right pleural cavity, the right lung completely collapsed and the right pleural cavity contains thirty-eight ounces of clear serum; there are bands of old loose adhesions at the apex of right lung and spinal column. Base of left lung adherent to diaphragm. Heart normal in size; tissue anemic and contains fat; valves competent. Lungs: Right—There is an opening in the upper portion of the lower lobe in the axillary line, about one-eighth inch in diameter, communicating with a cavity beneath. This opening is valvular, the valve so arranged as to prevent material entering from the pleural cavity. The upper and middle lobes contain many small cavities surrounded with pigmented fibrous tissue, many small tubercles and cheesy nodules. The lung floats below the surface of the water. Left—Permeated by milliary tubercles and small cavities, especially the upper lobe.

Dr. Robinson remarked that the hydro-pneumothorax was discovered only at autopsy. With reference to treatment, when recognized during life, there is a difference of opinion concerning the propriety of puncturing the chest wall for the purpose of removing fluid. He thought the weight of evidence was in favor of allowing it to remain rather than to open the chest.

PYONEPHROSIS.

Dr. John A. Wyeth presented the kidneys, with the ureters and the bladder, removed from the body of a man twenty-six years old, who had been in good health up to two years ago, when he came to Dr. Wyeth complaining of hemorrhoids, which he cured by operation. About three months afterward the patient complained of frequent desire to pass his urine—was obliged to get up three or four times during the night for the first six months. After that, rises of temperature developed, the patient became emaciated, and with frequent micturition continued through the next six months. Examination of the chest revealed slight consolidation at the apices of the lungs.

The autopsy revealed pyonephrosis and chronic cystitis. The pelvis of one of the kidneys was enormously dilated. Dr. Wyeth raised the question with regard to the propriety of performing cystotomy in such cases. Sir Henry Thompson had spoken favorably of it.

Dr. Van Gieson referred to a paper read by Dr. J. C. Hutchinson, of Brooklyn, in which was given a summary of cases, and his conclusions were favorable to the operation; the median operation for lithotomy with dilatation of the prostate.

Dr. Wyeth said he should perform the lateral operation, because the median does not give so good drainage. Dr. Van Gieson thought that was the very reason why Dr. Hutchinson preferred the median operation. Dr. Garrish referred to a case in which he operated as for stone in the bladder, and the patient made a good recovery.

Dr. Peabody spoke of the recognized value of the operation in women. But the question propounded involves a graver question than the surgical procedure, and that is the possibility of eliminating the condition of the kidneys found in Dr. Wyeth’s specimen. He thought that, at present, we do not possess clinical means by which we are able to say positively whether there is or is not a normal condition of the kidneys.

The President thought that if kidney disease was present the operation was contra-indicated. Dr. Wyeth did not see why this condition should contra-indicate the operation, as the patient might better have the rest afforded by the operation than the distress without it, such as the condition of the kidney is an inevitably fatal one.

The Society then went into executive session.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, December 5, 1883.

Dr. Samuel Sexton, President, pro tem., in the Chair.

Dr. William T. Bull read the paper of the evening, entitled

THE INTRAVENOUS INJECTION OF SALINE SOLUTIONS.

[The paper is published in full in The Record, January 5, 1884.]

Dr. Bull did not think that any air would get in, although even if a little did enter it would do no harm.

In answer to a query why the central end of the artery was injected instead of the peripheral, Dr. Bull said that the reason was that injection of fluid into the peripheral end had been attended with serious consequences, such as embolism and gangrene. It required a great deal of force also to inject the fluid into the peripheral end, while there is no difficulty in injecting the central end.

With regard to a query put by Dr. A. A. Smith, as to the difficulty of finding a distended vein and inserting a canula, he had had no trouble in the cases referred to. He had, however, experienced difficulty at other times, because he had generally delayed the operation of transfusion to the last moment, when the patient was exanguined. With the present method there was no need of waiting and there should be no trouble generally in finding a distended vein. He thought it important to examine both arms. The speaker knew of only two cases where arterial transfusion had done harm.

Dr. A. A. Smith had performed transfusion of desinfibrinated blood and had been fortunate enough in both cases to reach the vein, though with some difficulty.

Dr. William M. Polk said that his experience had been like that of Dr. Smith’s. It was with some difficulty that he could get into the vein, and doubtless because he postponed the operation too long. He had thought that the use of saline solutions offered many advantages over that of desinfibrinated blood, and he was disposed to accept it as a substitute for the latter.

As regards the value of transfusion after post-partum hemorrhage, he had seen but two cases of post-partum hemorrhage in his life, and in these the hemorrhage was easily controlled by the ordinary means.

Dr. C. L. Dana asked if there was any advantage in the intravenous injection of saline solutions over the injection of milk. The latter fluid had been highly recommended some years ago, but not much was said of it now. He had seen transfusion of milk practised in one case of severe hemorrhage from wound of the femoral artery. Intravenous injections were indicated here if at any time, and milk was employed, but without success; the patient was temporarily improved but soon after became worse again and died. He questioned if saline solutions could do any more than milk, unless perhaps it were shown that larger quantities of the former could be safely injected.

Dr. Bull said that it was as hard to get milk that was pure and fresh as it was to get blood. The use of milk had for this reason, in part at least, been abandoned. The specific gravity of milk and of the saline solutions was very different also.

Dr. R. F. Weir said that his experience with the intravenous injection of saline solutions was confined to two
cases. Although these both terminated fatally, yet in one of them there was decided temporary improvement. In cases where transfusion was indicated he would recommend the use of saline solutions.

Dr. Weir related the

HISTORY OF TWO CASES OF LAPAROTOMY FOR INTESTINAL OBSTRUCTION.

[These cases will be reported in full in The Record.]

In the discussion, Dr. J. B. Hunter asked what was Dr. Weir's method of closing the abdominal wound.

Dr. Weir said that he used half a dozen sutures, closing the pouting in the abdominal wall with finer superficial sutures.

Dr. Hunter had been surprised to see a good many cases of imperfect union of the abdominal walls, this showing itself some years later. It was due, he thought, to imperfect union of the peritoneum. He had been accustomed, of late years, to put in the deep silver wires, then close the peritoneum with catgut sutures. You make sure in that way of preventing the passage of anything into the peritoneal cavity. In a large number of cases treated thus there had been perfect union of the abdominal walls by first intention.

Dr. Weir said that he was struck, when he saw Lawson Tait operate, with the extreme

SHORTNESS OF HIS INCISIONS.

In some cases they were only one and a half inch, in others two to a half a tait. Tait laid great stress upon this, not for the safety of the operation, but for the future comfort of the patient. He closed the wound in his ordinary way.

Dr. Hunter said that that point was dwelt upon very emphatically by Spencer Wells, who asserted that the shorter the incision the less the danger from peritonitis.

Dr. Polk said that there was great difference of opinion among good authorities as to whether the peritoneal surfaces should be closed or not. The question is one of a great deal of importance in ordinary laparotomy. In cases of ovarian tumors the peritoneum generally is easily brought together, but in other cases like those of Dr. Weir's, or where the patient is fat, it is a different matter, and he was satisfied that the surfaces were never brought together. Even when the surfaces are thus opposed, the points of suture furnish opportunities for pus to enter the peritoneal cavity.

Dr. Polk said that he last a patient about six months ago just from his determination to get the peritoneal surfaces together. The woman was very fat. The incisions were made in the usual way, and the ovarian tumor removed without any trouble. It was a very simple and uncomplicated operation. After he had put in all the stitches except the two lower ones, he slipped in his fingers and found that the peritoneal surfaces were not together at all. He attempted to bring them together with catgut sutures, but the minute he made any tension the catgut would simply tear out. The manipulation, he believed, aided in part in causing the formation of an abscess, which broke into the abdominal cavity and killed the patient. He believed, therefore, that where peritoneal surfaces can be done easily it was advisable, otherwise not.

Dr. Weir said that Tait quotes some seventy cases, without any death, where the sutures were put in the ordinary way.

Dr. A. A. Smith thought that it did not make any difference in the result whether the peritoneum was sewed together or not, except from the especial manipulation which that operation required.

Dr. G. F. Shady reported a

CASE OF DIPHTHERITIC CAST OF THE BLADDER PASSED THROUGH A PERINEAL OPENING.

The patient, a male, aged forty-five, was admitted to the Presbyterian Hospital suffering from extravasation of urine, the result of rupture of a strictured urethra.

The accident occurred during a fit of intoxication two days before. The usual operation was at once performed for his relief. He progressed favorably for a month, during which time a large slough of the perineal tissues separated. Soon after he was suddenly seized with retention, which was occasioned by what appeared to be valvular plugging of the perineal opening. A catheter was passed through the wound, and a considerable quantity of foul-smelling urine was evacuated. A few hours after this, during an attack of vesical tenesmus, a foreign substance protruded itself through the perineal opening, and was removed by the patient. This mass proved to be a complete cast of the lining membrane of the bladder. During the time when this exudation had been forming there had been no constitutional symptoms, nor did any blood follow later. The mass was so much decomposed that no satisfactory microscopic examination could be made. It was quite evident that it was exudative in character rather than a slough of the mucous membrane proper, for the reason that there were none of the constitutional symptoms present indicating the graver trouble. The patient made a perfect recovery without a repetition of the exudation.

Dr. Sharkey believed that this accident was a very rare one in the male, and, as far as he knew to the contrary, it was unique under the circumstances mentioned.

Dr. Weir said he had seen such things in the female, but not in the male.

Dr. Hunter said that the late Dr. Peasele had once presented a specimen of a uriniferous cast of the rectum, which he obtained from a woman who had had dysentery previously, but did not live at the time when the cast was passed.

Dr. Ball said that the passage of more or less perfect fibrinous casts from the rectum was not uncommon in women. He believed that they came from higher up than the rectum.

Correspondence.

OUR LONDON LETTER.

(Special Correspondent.)

SIR ANDREW CLARK ON CATHERETER-FEVER—PROFESSOR FLOWER—PNEUMOTHORAX AND PHLEBISIS—THE HAFFENDEN-HARDIE CASE.

LONDON, December 4th, 1885.

The subject of so-called "catheter-fever" has again been brought forward by Sir Andrew Clark, who delivered an address on this topic at the last meeting of the Medical Society of London, December 17th. An interesting résumé of the history of the subject was given. Sir Andrew Clark's contention is that the commencement of catheter life may be followed by fever which, occurring in patients apparently in good health, may speedily prove fatal without the occurrence of any morbid lesions discoverable post-mortem. He noticed that in his cases the urine was of low specific gravity. The patients were middle-aged men who had for some time suffered from chronic bladder trouble, due to the incomplete emptying of that viscus.

An interesting discussion followed. Sir Henry Thompson objected to the term "catheter-fever" and maintained that the condition, although supervening at the commencement of "catheter life," was due to the fact that the use of the catheter had been postponed too long, and "had the catheter been used when there were only six or eight ounces left in the bladder, we should have heard nothing of catheter-fever." Sir Andrew Clark's views evidently did not meet with unqualified approval, especially as regards the pathology of the disease. Had they been brought forward by a less distinguished physician they would probably have attracted little attention.
Mr. Savory referred to the importance of ascertaining the state of the kidneys before performing serious operations, and especially of estimating the quantity of urea excreted. He said that "with regard to serious operations, or in considerable shock to the patient, I would rather have thoroughly sound kidneys on my side than ev'ry sound heart or lungs."

In reply, Sir Alfred W. S. B. Jowett explained that he did not object to the use of the catheter and agreed with Sir Henry Thompson, that many of the difficulties arose from its not being used early enough. He coincided with Mr. Savory as to the importance attaching to the condition of the kidney when surgical operations were contemplated, and said it was a point he had brought forward twenty-eight years ago; and on various occasions since, under the term of "renal inadequacy," he had pointed out the great peril of performing surgical operations in such cases. The discussion is to be resumed at a subsequent meeting of the Society.

It is rumored that Professor Flower is to succeed Professor Owen at the Natural History Museum, South Kensington. It may be remembered that when Professor Flower succeeded Professor Owen in the post he now holds, viz., Curator of the Museum at the Royal College of Surgeons.

An interesting discussion took place at the Clinical Society on December 14th, on pneumothorax. Sir Andrew Clark mentioned some cases of phthisis in which the progress of the disease was checked for a time by the presence of pneumothorax.

Mr. Haffenden-Hardie's case has ended in a verdict of "Not Guilty," after a very brief deliberation of the jury. It may be remembered that the late Mr. Haffenden (who committed suicide) was charged with procuring abortion on Mrs. Hardie, the other defendant. The prosecution was put up by a neighborhood practitioner, who had been called in to the case in Mr. Haffenden's absence. The evidence seems to show that Mrs. Hardie was aware or suspected that she was pregnant. Mr. Haffenden, however, from her statements, was led to think she was suffering from a uterine tumor, for which he gave ergot and employed the uterine sound. A miscarriage followed. There is no reason to suppose that Mr. Haffenden endeavored to procure abortion or had an idea the patient was pregnant until afterwards, and probably no aspersion would ever have been cast upon him but for the conduct of a professional brother and for the precipitate action of the Public Prosecutor, who certainly should have taken the advice of an expert before sanctioning the prosecution of a medical man of unblemished reputation on such a charge. The Public Prosecutor seems to have acted equally unwisely in the Bower-Keates case. Indeed, if his conduct in these two cases is an average, the sooner his office is abolished the better.

TREATMENT OF CEREBRO-SPINAL FEVER.—Dr. J. Lewis Smith sends us the following interesting private letter which he received from a correspondent, Dr. Robert B. Smith, of Tioga, Pa.: "In 1872," he writes, "we passed through an epidemic of the disease, with an average mortality of about thirty-eight per cent. A singular feature of our epidemic was the number of cases of sudden death. Quite a number of my patients at about the eighth or tenth day, who to all appearances were doing reasonably well, would be suddenly taken worse and die within thirty minutes from the time that any change was noticed in their condition—they died without convulsion. I could only account for it on the supposition that the inflammation had invaded the medulla and disturbed the pneumogastric. As the epidemic progressed, the physicians here used opium more freely, some to the extent of continued narcosis, and the death-rate diminished. Either the disease had expended its intense force, or the opium treatment had a happy effect."

SIR: A nation's history is perpetuated in the names of her illustrious men, and the history and fame of her great and good are beacons which light the kindling spark of genius in its ambition. The peaceful triumphs of art may better wear the crowning laurel of fame, than any wrested from political faction or torn from circumstance in sanguinary war.

Dr. J. Marion Sims was a hero, though of gentle men and character.

He dared to do for his race what had never before been formulated in such a manner as to attract the attention and labors of others in his profession, men who have, by the inspiration of his genius, won meritorious fame.

Who will not do himself honor in raising his hand to inscribe the name of J. Marion Sims upon the altar of immortal fame, that future generations may know, as we who are living and knew him in the flesh do well know, that his merited fame was as broad as the civilized world; that his character was great, his power big, his sympathies responsive.

There can be none upon whose lips ever dwelt the endearing name of mother who will say that Sims' noble life was not one of unswerving devotion to the amelioration of women's sufferings.

Few have ever been so loved by their professional brethren, throughout the length and breadth of the land, and few have had in them combined the qualities of greatness with so many lovable traits of character.

As an earnest of the desire to see a monument erected in Central Park to the memory and fame of Dr. J. Marion Sims, a contribution of one hundred dollars, each, from Dr. R. S. Sutton, Mr. George Westinghouse, Jr., and your correspondent, will be handed to a committee as has been wisely suggested in your journal of January 5, 1884, by Professor S. D. Gross, of Philadelphia.

With most respectful consideration, believe me,

Yours truly,

W. H. DALY.

PITTSBURGH, January 6, 1884.

[It will be seen by the No. for January 14th that a committee has been organized, and that THE MEDICAL RECORD is ready to receive subscriptions to the fund.—Ed.]

THE NEW YORK COLLEGE OF MIDWIFERY, ITS PAMPHLET ENTITLED "WOMAN'S WORK," AND ITS "CONFIDENTIAL" CIRCULAR TO THE PROFESSION AND LAITY.

To THE EDITOR OF THE MEDICAL RECORD.

SIR: When the "College of Midwifery" was organized we accepted the offices of censors, believing the institution and its object worthy of our recognition and assistance. Our connection with the institution had been but brief, when we already found it necessary to criticise severely some things in its organization and management. Our position as censors gave us no voices in the conduct of the institution, our duties being simply to be present and assist in the examinations.

The title and character of the pamphlet mentioned above met with our disapproval when first seen after it was in print; and the circular and "confidential" card which have been distributed to the profession and laity, issued wholly without our knowledge, and only accidentally seen by us to-day, meet with our most emphatic disapprobation to such a degree as to determine us to dissolve our connection with the College in which we have done by forwarding our unconditional resignations to-day.

B. F. DAWSON, M.D.
PAUL F. MUNDE, M.D.
CONCERNING NEWPORT AND ITS SUPPOSED "MILD WINTER CLIMATE."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The Record of December 22d has an article on the "Mild Winter Climate of Newport, R. I.," etc., by Dr. H. R. Storer, in which he first refers to his previous publications on the same subjects, and states that "they conflicted with another person's preconceived theory." This manner of referring to gentlemen would ordinarily call for silence only, but for the sake of the cause of the climato-therapy of consumption, permit me once more to hold Dr. Storer's bait up to the gaze of the profession. In the article referred to, Dr. Storer attempts only to establish a comparatively mild winter temperature for Newport, based upon the fauna and flora, the southern characters of which prove the proximity and influence of the Gulf Stream. My arrangement in answer is as follows:

First.—In all previous articles Dr. Storer distinctly referred to consumptives as those likely to be benefited, and not of "delicate people and convalescents." His appeal to me by letter at that time was in favor of a "mild climate" nearer home for persons of more or less limited means. Now the appeal is for "delicate people," and the recommendation is of "mildness," when previously it was claimed that Newport possessed the stability of temperature in common with southern latitudes.

Second.—Any one who pretends to know anything of climatic effects knows that there are only three elements to be considered, namely: dryness, equability of temperature, and elevation. Heat and cold, as such, are individual conditions felt more keenly, in the presence of moisture than by the man who is in the presence of dryness and a steady inequality of temperature. To tell us now that in January Newport is a third of a degree warmer than New York is certainly funny. One-third of a degree of difference in temperature in moist climates is what a blessing!

Finally, let me sum up. No one objects to an advertisement of Newport as having a mild climate with one-third of a degree of difference in temperature between it and New York, but many more delicate consumptives, of course, than Dr. Storer do object to having the subject of climato-therapy relegated back to the darkness of the middle ages.

Very truly yours,

J. HILGARD TYNDALE, M.D.

36 EAST TWENTH STREET.

"PREVENTION OF Puerperal Fever."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In view of the great danger to the puerperal woman from infection through the genital canal, and the very great difficulty experienced in employing proper prophylactic measures, as so clearly elucidated in the past recent reports before different medical societies in New York, I would like to suggest through your valuable paper that the Academy appoint a committee to investigate the advisability of instructing the "gentler sex" (and if thought necessary make it compulsory) to wear an anti-septic pad over the vulva from the inception of the catheterization. It is to be removed without any strict anti-septic precautions, but by using the carbolic spray. Yours in science,

SETH HILL.

P.S.—This suggestion does not arise from a theoretical standpoint by any means, for I have a patient under such treatment, and as she escaped the fever I think it a move in the right direction.

STEVENS, CONN., December 16, 1859.

SHAKESPEARE AND APOLECTIC SEIZURES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In The Record of the 12th inst. one of your contributors uses this language: "Three drops of croton-oil were laid on the old man's tongue and his temples were liberally festooned with leeches till I could not but think of the poet's exclamation, 'Shake not thy gory locks at me.' The poet never exclaimed in this style, if Shakespeare is the poet from whose writings the quotation is intended to be. In "Macbeth," Act III., Scene 4, these lines occur: "Thou canst not say I did it: never shake thy gory locks at me."

Probably no author is so often improperly quoted as Shakespeare. Only a few days ago a medical friend, in the course of a conversation, remarked, "Discretion is the better part of valor." Falstaff, "King Henry IV.," Act V., Scene 5, says: "The better part of valor is discretion; in the which the better part I have saved my life."

HYDROGEN DIOXIDE (H₂O₂) IN THE TREATMENT OF VENEREAL DISEASES AND AS A TEST FOR PUS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: My object in this brief article is to call attention to the use of hydrogen dioxide (H₂O₂) or oxygenated water, in the treatment of venereal diseases, as a local application for venereal sores, and as an injection in gonorrhoea; also as a positive and simple test for the presence of pus in urine or any other fluid.

Although hydrogen dioxide, or hydrogen peroxide as it is generally called, has long been known as a chemical compound, yet it has had no rank as a therapeutic agent until lately. It has been brought to notice as a bleaching agent for hair, changing black hair to a light color, by reason of its great power of destroying vegetable coloring matter.

My attention was particularly directed to this agent by the report of M. Miguel, of the Observatoire de Montsourir, in which he shows the minimum quantity of the different antiseptics capable of preventing the development of germs and bacteria. In these experiments, H₂O₂ is recognized as being the most powerful destroyer of germs. In this respect its value has been recognized by dentists as a mouth-wash, it being introduced into this city by A. W. Harlan, D.D.S.

A few drops of peroxide of hydrogen brought in contact with pus will produce an effervescence similar to that caused by hydrochloric acid on a carbonate. The action continues until all the pus is destroyed, so that it cannot be recognized microscopically.

My first experiments with this agent were as a test for pus in urine, it is the simplest and most delicate test, the smallest quantity of pus being easily detected.

As an application for venereal sores I recognize its chief value in the fact that it answers every purpose of the caustics and escharotics used in the treatment of these diseases, at the same time being less destructive. When applied to a suppuring sore, a rapid effervescence commences and continues until the sore is perfectly cleansed, leaving the tissue beneath ready to be healed by any simple application. My observations with this remedy extend over twenty cases of chancreoid, all of which were relieved in a short time without the use of caustics or iodiform, and without pain to the patient. My treatment consists in applying H₂O₂ to the surface of the sore until all effervescence ceases, then cleansing the parts with plain water and applying a mixture of vin aromatic, glycerin, and rose-water in the following proportions: Vin aromatic, 3 j.; glycerin, 3 j.; rose water, 3 v. In the majority of cases the healing process commences at once, and in a few days the sore is entirely well.

In the treatment of chancre it cleanses the surface and
puts it in condition to heal under proper constitutional treatment. As an injection for gonorrhea, alternating with an astringent injection, its use has proved most satisfactory. Later I propose to give a detailed statement of its use in thirty cases of chancreoid and ten of gonorrhoea treated in my practice. Peroxide of hydrogen is destined to become an important agent in the treatment of any suppurating sore, not only on account of its power to destroy pus, but because of its great anti-septic properties.

ROBERT W. STEGER, M.D.
146 STATE STREET, CHICAGO, ILL.,
October 14, 1883.

AN APPARENTLY NEGLECTED PRECAUTION IN THORACENTESIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: The following notes may prove interesting, and perhaps instructive, to some of your readers: M. L., boilemaker, fifty years of age, consulted me, November 30th, at the Manhattan Eye and Ear Hospital, Department of Nervous Diseases, complaining stiffness and pain in the shoulders and back. One year before he had been exposed to wet and cold. Then, and ever since, he had suffered from pain in the upper dorsal spine and under both scapulae, more under the right. These pains were worse on motion, in stooping, at night and in bad weather. He had water-brash, no appetite, and was constipated. Had never had any fever, chills, sweats, or cough to speak of. He was incapacitated from work by the pain any movement caused him, from weakness or general debility. His general nutrition and appearance were so good that his wife thought him shammying and lazy, and deserted him. He spent all his money in useless treatment, and at last turned up with only a worn-out chair at the medical office on LaSalle Street. At the first visit he lost his watch and chain, after a few more he began to lose his teeth, and after six months he lost confidence.

Wishing to examine the ailing parts I made him strip, which he did with difficulty. I immediately noticed a bulging of the lower part of the right chest, which from ordinary physical examination I took as being a contained fluid. A tracing of the chest, taken with a cytometer, showed a bulging on the right side most marked at the posterior border of the axillary line. The right chest, at the level of the ensiform cartilage, had a circumference three centimetres greater than the left. The right shoulder was raised and the right chest expanded less than the left. The vocal fremitus was about normal on the right side except in the lower axillary and inframammary space where it was absent. There was dulness on percussion on the right side at the seventh intercostal space in the axillary line, at the sixth intercostal space in the nipple line. Below this line there was almost complete flatness. This line of dulness and flatness shifted according to the position of the patient. In the region of flatness there was no vocal resonance. On two occasions I withdrew from his thoracic cavity, with a large hypodermic syringe, some clear serum. The last time I aspirated him successfully in the presence of Drs. Birdsell, Adam, Muzzy, Ray, Swift, Mead, and Sarloubs.

I sent this patient to two hospitals for treatment. At one he was refused admission by the examining intern as a case of locomotor ataxia, and when sent back with a polite request that he be carefully examined he was admitted, aspirated, and discharged the next day, house-staff and attending physicians agreeing that the chest contained no fluid. At the other hospital he was admitted but no fluid was found.

Now the failure to obtain fluid in this case depended upon ignorance or neglect of a point which I thought everybody knew. The mistake consisted in introducing the needle to its full length, exhausting the syringe and getting no fluid, from the mere reason that in all probability the point of the needle was imbedded in the lung.

The way in which I invariably got fluid was to introduce the needle to its full length, then exhaust the syringe and, keeping up the exhaust, slowly withdraw the needle till a point was at length reached where a sudden gush of serum occurred, showing that a thin stratum of fluid lay between two thickened pleuric or between the chest-wall and a lung bound down by adhesions.

It was a matter of surprise to me that the presence of fluid, even in small amount, could not be detected by ordinary physical signs (a line of flatness changing its level by a change of position), and also that aspiration by such skilled hands should have so signally failed.

R. W. AMIDON, M.D.

MEDICAL PRACTICE IN MEXICO.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Malignant intermittent or pernicious fever is not as frequent here, in Northeastern Mexico, as it is in the lower valley of the Mississippi and some parts of Texas, nor does it have the same mortality as fatal in its effects as in those parts of the Southern States where I have practised before. Of course, the disease is one of those that fill even the experienced practitioner with dismay, but I have had better success in this city in the treatment of it than I had in Texas or Louisiana. This may be due in part to my strictly avoiding the use of blisters, which involve the risk of death by our waiting for their effect, which hours are invaluable in such cases where the fatal termination may take place at any moment. Long ago this had suggested itself to me, and I substituted accordingly the application of near boiling hot water to the feet and hands. But even this is often not readily obtained, and consequently I sought and found the equivalent in the application of Paquelin's thermo-cautery. This is ready for use in a few minutes and its effect as a revulsive always sure. The first time I resorted to it was in a very trying case. I found the man, who had, as I was then informed, for several days already suffered from intermittent fever, in a comatose condition so that the pulse was present only through slight shaking of the fingers. He had a severe rigidity of muscles and afterward a high fever, during which the convulsive movements continued and loss of consciousness ensued. This impressed them with the idea that it was rather more than common chills and fever, and so they sent for several medical men without meeting any until they finally found me. As there was no hot water, and nothing at hand to use in such a contingency, I hurried home, got my thermo-cautery, and after I returned put it in working order as rapidly as possible. I applied the button at once to the calves of the legs, along the lumbar vertebrae and the soles of the feet. To my great satisfaction a short time after and while I was reflecting yet whether I ought to use it more extensively or not, the man gave signs of suffering pain, and with one hand felt toward one of the points I had touched with the platina button. The rest of the treatment it is hardly necessary to dwell upon. Full doses of quinine by the mouth and enemas of the same in solution introduced high up into the rectum by means of an elastic catheter attached to a syringe, cold to the head, etc., were about all that was employed. My patient safely weathered the dangerous point, and I have had since then an opportunity to follow the same treatment repeatedly and almost invariably with good result. The burns of the button are small and in my cases always healed readily without ulcerating. As the instrument is in these cases, not to destroy any thing, it should be applied only to the skin instant only. This treatment may seem too heroic at first sight, but in reality its effects are not as severe as those of large blisters, which may cause a protracted ulceration.
and other disagreeable consequences, to be mentioned further on.

Remittent fever is much more frequent here than pernicious, and I have had during several years a large number of cases to attend to. Many of these were quite formidable, but in some cases a good deal of judicious management. But I believe I do not go too far if I say that in no cases of severe sickness the assiduous attendance of the physician can do more good and finds itself better rewarded than in the grave cases of this kind. My principal guide is the thermometer. Observing carefully the rising and falling of the temperature, I direct my remedies accordingly. My old friend and teacher, the late Professor Fenner, of New Orleans, who had an experience in this class of diseases rarely equalled, expressed it as his opinion that remittent fevers would not occur so frequently if the preceding intermittent was cut short in time. My own experience has taught me the correctness of that excellent gentleman's views. If, at the beginning, the intermittent is cut short, a remittent will not develop itself, even though in the surrounding of the patient cases of remittent exist at the time. I have had at least two examples here which illustrated this to my satisfaction. The difficulty about these remittents is their tendency to prolong themselves, to become more serious from day to day, until they gradually pass into a consumptive state.

In fact, there is no difference to be observed between these two diseases after a certain lapse of time, say from fifteen to twenty days, and the question is hard enough to decide where and when remittent cases and typhoid begins. I do not wish this to be understood as applying to all cases of remittents. There are always many, or a much less serious order, and there is even a difference in the character of the disease at different parts of the year and at different years.

I mentioned above that I rely principally on the indications of the thermometer. Whenever I find the temperature above 39.5 C. I abstain from the administration of quinine and limit myself to the use of a strong decoction of yellow Peruvian bark (1/4 oz. to 8 oz. water), in which from three to four draughts of benzoate of soda are dissolved, a tablespoonful every hour. If, after the lapse of six hours, the temperature has not diminished, I resort to cold packing, which almost invariably reduces the heat to the extent of 1 or 1.5 degree. As soon as I can obtain tubular, I will often baffle all efforts to overcome these remittents speedily. Quinine, if given at a high temperature, is liable to produce unpleasant symptoms. Repeatedly it has occurred to me that a semi-comatose state or great excitement followed its administration. For this reason I give the decoction of bark, etc., which gradually reduces the temperature and prepares the final annihilation of the quinine, which serves to fortify the position gained against further attacks and guards it against a recurrence. This treatment has but rarely disappointed me. Blisters I have not used in this disease for a number of years past, and I honestly believe that I owe in part to this non-interference of mine my favorable results.

Typhus I have never seen here and I might almost say the same of typhoid fever. Of the latter I had only few cases, and these were managed with more ease and ran their course more mildly than at other places where I practised before. I do not include in this the cases of remittents which became typhoid.

A very formidable disease, which is not very unfrequent here and is very well marked, is the bilious typhoid, described by Griesinger in his celebrated work on infectious diseases. I have followed his treatment with good success and, [although not all my patients recovered, the majority of them came through safely. The people of this part of the country are justly afraid of this disease, which erroneously they call malignant jaundice (icterus gravidus). But it is not the icterus gravidus such as is met with in other countries, as there is always considerable enlargement of the spleen and no atrophy of the liver.

I have above given expression to the opinion that my success in treating fevers in Southern countries had become much better since I had ceased to resort to the old time-honored use of blisters. I go so far as to say that I think the time has come to limit their use, in the same way as the profession in our days has reduced venesection to certain indications only. The question is an open one, which of the two remedies may do more harm, if indiscriminately applied in such diseases as infectious or eruptive fevers. In this country the popular idea is that the heat is the disease and that the urine takes place. The people are so accustomed to this result that they look upon it as a logical sequence. Nor is this opinion erroneous. I know that there is no symptom more alarming to me in yellow fever, typhoid, remittent, or bilious typhoid. The kidneys are naturally seriously involved in these fevers with a high temperature without intermission. If after intermission there is a juncture in the shape of blisters, the functions of the kidneys must inevitably become more seriously impaired and even suspended, the disintegration of these important glands having really begun. Thus a dangerous disease, but which might have been managed so as to lead to a favorable result, is now complicated with albuminuria and the life threatened by uremia or cedema cerebri. It looks like quite an innocent matter to use one or several good-sized blisters, because everybody did and does apply them, and often the physician and the public think everything safe if it has taken while, in reality the danger has only been increased by it. For these reasons I unhesitatingly give it for the impression that the use should be limited to certain indications only, in the same way as has been done with venesection and the excessive use of calomel.

EDMUND GOLDMANN, M.D.
MONTREAL, MEXICO, October 13, 1883.

THE MICROCOCCI OF ALOPECIA form the latest addition to the pathogenetic bacteria. Dr. O. Lassar concedes that baldness is spread by hair-dressers who employ combs and brushes on their customers, one after another, without any regular cleansing of these articles after they are used. Hair which fell from heads in which dandruff occurred plentifully were collected and rubbed up with vaseline. The ointment thus made was applied to the fur of rabbits or white mice. Soon baldness made rapid progress in the parts so treated. Vaseline alone produced no effect.

ACID MOTHERS.—Dr. S. A. Evans, of Conway, N. H., writes: "Having noticed, in The Record of December 8th, 'the case of a woman who gave birth to a child when forty-eight years of age,' reported in the British Med. Jour., I am moved to report two cases which occurred some years since, in this town, of women fifty years old, who gave birth to living children. The facts are well known and can be proved beyond doubt. Both cases occurred in the same family connection, and the history of the family for several generations shows it to have been remarkably prolific."

LUNACY IN FRANCE.—In France there are now 103 lunatic asylums, 61 of which are public and 42 private. Nine of the total are exclusively for men and 14 for women, the rest being for both sexes. During the last fifteen years a considerable increase in lunacy has occurred in France. There were 34,000 lunatics in 1868, and there are now 60,000.

SOMETHING TO BE REMEMBERED NEXT SUMMER.—Deconnection of quassia, applied to mosquito bites, constitutes an excellent remedy for the relief of itching and irritation. When applied to the exposed portions of the body it is also a preservative against the attacks of these very disagreeable and annoying insects.—Journal de Médecine de Paris, November 17, 1883.

LABOR AT THE END OF THE SEVENTH MONTH WITHOUT RUPTURE OF THE FETAL SAC.—Dr. E. F. Cowger, of Riverton, Ia., sends us the report of a case as follows: "I was called September 8, 1876, to attend a healthy young woman in her second confinement. She, the day previous, while stepping out at a door slipped and fell quite a distance, and in a few minutes after her fall she noticed a flow of blood from the vagina. During the following night labor pains set in and I saw her about noon the next day. She claimed that she was only at the end of the seventh month, and, from circumstances not necessary here to relate, and from the development of the child, I believe her statements were true. Having quite a distance to go I only got into the room when the child was born, with placenta and with the membranes intact. Thinking the child dead, and judging from the appearance of the mother that she needed my immediate attention, I first examined into her condition, and while making this examination I noticed that the sac moved. I at once ruptured the membranes, cut the cord, but did not then tie it, and removed the child, which I noticed was making some effort to breathe, wrapped it up warm, and laid it out of the way, and then attended to the mother who was flooding quite freely. After making her as comfortable as possible, I went to the child and to my surprise found it breathing, though very feebly. I left instructions with the nurse not to disturb it until I again saw it, and to keep it warm. I called the next day, when we washed and dressed the babe, and to-day he is a fine large healthy boy. The mother made a good recovery."

THE AMOUNT OF CARBONIC ACID Generated by lights is thus represented: Electric lights, none; argand gas-burner, .46; flat-flame petroleum, .95; colza-oil light, 1; paraffine candle, 1.22, and tallow candle, 1.45. It has been remarked that the tallow candle, the oldest of these artificial lights, is not only the hottest but the most unhealthy.

UPHOLDING THE PATENT MEDICINE TRADE.—The druggists of Oneida, Madison, Herkimer, and Otsego Counties have formed an association for mutual protection in handling patent medicines. Each druggist pays twenty-five dollars on joining the association, and agrees not to sell any patent medicine below standard prices. The penalty for violating the agreement is forfeiture of the initiation fee and membership. The members of this druggists' union say that competition has rendered dealing in patent medicines unprofitable to all—including probably the customers.

THE TREATMENT OF THE PLACENTA AFTER DELIVERY.—Dr. W. P. Giddings, of Gardiner, Me., writes: "Noticing in your valuable journal of December 29th an article from the Deutsche Med. Wochenschrift, by Dr. Dohnr, on leaving the placenta for nature to remove, I am induced by it to add my strong endorsement of this method. In quite an extensive obstetric experience, I have adopted three several methods for the delivery of the placenta, viz.: following for the two first years of my professional life the one taught me by the late Prof. Buckingham, of Harvard, instruction to deliver at once, by compression and gentle traction upon the cord; second, Credé's; and last—and to my mind the best—leaving it to nature. In the last method, I would, with my left hand the contracting womb as the child is expelled, to insure the safe contraction, then entrust it to the nurse or some competent person while I tie and separate the cord. Having disposed of the child, I again place my hand upon the uterus, to make sure it does not unduly relax, and await its efforts after a natural period of rest. During six years I have followed this plan with not a single accident, or a delay of more than twenty minutes, with a single exception, and that was thrown off at the expiration of fifty minutes with no other inconvenience than weary waiting. Contrary, however, to Dr. Dohnr's experience, I think a little more blood is lost than when Credé's method is adopted, but I have come to look upon that as more than necessary. The placenta has made more rapid recoveries than when the case was hurried. I will add that after delivery of the placenta, I always hold the uterus down until permanent contraction is secured."

THE INFLUENCE OF DIATHESIS UPON CONTAGION.—Dr. L. J. W. Lee, of Bridgeport, Conn., writes: "In perusing the inaugural address of Dr. S. Oakley Vander Poel, President of the New York County Medical Society, I was forcibly reminded of an incident which occurred in my practice some years ago in the Eastern District of Lyn, N. Y. The president, in speaking of pathologic and clinical studies, also 'asks the doctors not to lose sight of those broader diathetic manifestations, which will, from the same apparent cause, produce different diseases in different persons.' I may perhaps not touch upon the identical idea of Dr. Vander Poel, yet my experience may be worth noting. In the course of my practice as above mentioned, I at one time had ten patients under treatment in one house, and nearly each one suffering from a different disease, seemingly taken from the one poisoned atmosphere. Among the number were three with confluent small-pox, one of a milder type, and one with varioloid. There were two with measles, one with varicella, one with typhoid fever; and one with remittent fever, of the malarial type."

TO CLEANSE THE GAFFE BATTERY.—Dr. F. A. Burrall, of this city, writes: "I find that by putting salt and water into the cups of the Gaiffe battery, after they have been used, the yellow sulphate of binoxide of mercury is readily removed from them. This method is a good substitute for the vigorous brushing and scraping which are otherwise necessary. Those who use this convenient faradizer will, I think, appreciate the benefit of this suggestion."
SUBNORMAL TEMPERATURE IN CERTAIN MALARIAL AFFECTIONS.

By J. W. STICKLER, M.D.,

The following cases, which although irregular as regards type, were ascertained to have a malarial origin, and which in their course were marked by a subnormal temperature, as they were all hospital cases, a statement of what was done for them, as well as of their physical condition from day to day, will most accurately present the cases to those who have not read the article.

CASE I.—Thomas H.—sixty years of age; English; widower; moderate drinker. Condition when admitted to hospital: Pulse, 86; temp., 100°; resp., 40. Thirsty, no appetite; unable to retain nourishment. Face flushed. Very restless. Urine: color, dark yellow; odor, natural; sp. gr., 1.010; reaction, faintly alkaline; precipitate of mucus, no albumen. Had a chill at 8 A.M.

September 7th.—9 A.M.: Temp., 103°; pulse, 60; resp., 30. 2 P.M.: Temp., 104°; pulse, 118; resp., 34. Face flushed. Very restless all the afternoon. At 10.10 P.M. took quinine, grs. x. Had frequent movements from bowels during evening, due to action of cathartic.

September 8th.—Slept very little during the night (of September 7th). Was troubled with nausea and vomiting when food was given. 9 A.M.: Temp., 96°; resp., 18; pulse, 11.40 A.M.: Took quinine, grs. x. Temp. at 7 P.M., 90°; pulse, 80; resp., 20. Very restless, pains in calves of legs and in left side.

September 9th.—7 A.M.: Temp., 97°; pulse, 75; resp., 24. 11 A.M.: Temp., 98°; pulse, 75; resp., 22. Ordered Warburg's tincture every three hours for one day.

September 10th.—7 A.M.: Temp., 97°; pulse, 58; resp., 22. In the afternoon, 3 P.M., the patient repeated at 6 A.M. 6.30 P.M.: Temp., 100°; pulse, 75; resp., 30. Perspiring freely, and constantly muttering.

September 10th.—7.15 A.M.: Temp., 99°; pulse, 64; resp., 24. 11 A.M.: Temp., 98°; pulse, 66; resp., 28. Ordered Warburg's tincture every three hours for one day.

September 11th.—7 A.M.: Temp., 97°; pulse, 58; resp., 24. In the afternoon, 3 P.M., the patient repeated at 6 A.M. 5 P.M.: Temp., 97°; pulse, 65; resp., 16.

September 14th.—7 A.M.: Temp., 97°; pulse, 74; resp., 14. 10.30 A.M.: Temp., 98°; pulse, 84; resp., 16. His condition was maintained at about the normal standard from last date.

CASE II.—John B.—fifty-three years of age; American; widower. In April, 1883, had an attack of cerebral pneumonia. Has lived in a malarial district, and has had intermittent fever. For several days prior to admission into hospital, had quotidian intermittent fever. Chill attended with pain in the back. Appetite fair. Face shrunken and pale. Bowels loose and watery. Temp., 100°; resp., 30; pulse, 76. Urine: odor, normal; color, slight. Sp. gr., 1.010; reaction, acid. No albumen. Ordered quinine, grs. x, to be repeated as occasion required.

September roth.—10.45 A.M.: Temp., 96°; pulse, 60; resp., 14. Had a small and partly formed alvine discharge. Feels the same as on other days when about to have a chill. At 4.30 P.M. had a severe chill, and immediately after it his temperature rose to 105°.

September 11th.—7 A.M.: Temp., 96°; pulse, 52; resp., 13. In the afternoon had a profuse perspiration without chill. 7 P.M.: Temp., 97°; pulse, 68; resp., 17.

September 12th.—7 A.M.: Temp., 98°; pulse, 74; resp., 22. No chill. Appetite good. 5 P.M.: Temp., 97°; pulse, 68; resp., 17. Bowels moved. Has had whiskey, ½ ss. every four hours.

CASE III.—Max C.—aged twenty-five years; Russian; single; hatter. Has always been healthy. Drinks moderately. Healthy in appearance. Has had for a few days quotidian intermittent fever. Urine: odor, natural; color, yellow; sp. gr., 1.010; reaction, acid; no albumen.

September 6th.—Temp., 99°; pulse, 74; resp., 24. Ordered quinine, grs. x, at 7 and 10 A.M.

September 7th.—10.35 A.M.: Temp., 97°; pulse, 48; resp., 28. Complains of pain in left side. Quinine, grs. x, every four hours. 7.15 P.M.: Temp., 97°; pulse, 54; resp., 32. Perspiring about face and neck; face cool.

September 8th.—7 A.M.: Temp., 96°; pulse, 50; resp., 28. Pain in left side under ribs is most intense when sitting. 6.30 P.M.: Temp., 99°; pulse, 50; resp., 28. Quinine continued same as yesterday.

September 9th.—7 A.M.: Temp., 97°; pulse, 58; resp., 28. No marked relief from pain in side. Headache and giddiness late in afternoon.

September 10th.—7 A.M.: Temp., 98°; pulse, 68; resp., 24. Pain in epigastric region, in right hip, and in right thorax.

September 10th.—7 A.M.: Temp., 98°; pulse, 68; resp., 24. Quinine has made him somewhat deaf. Quinine, grs. x, every three hours.

September 11th.—10.20 A.M.: Temp., 98°; pulse, 72; resp., 28. Had severe chill. Pain has disappeared from side. 7 P.M.: Temp., 99°; pulse, 72; resp., 22. After this date made a good recovery.

CASE IV.—Carlo M.—aged twenty-five years; Italian; widower. Last August had fever, severe pain in head and abdomen. Had a paroxysm of intermittent fever every second day of week of admission into hospital. Urine: odor, natural; odor, normal; reaction, acid; sp. gr., 1.018; no albumen.

October 12th.—7.30 P.M.: Temp., 97°; pulse, 80.

October 14th.—7 A.M.: Temp., 97°; pulse, 68; resp., 24. Still has pain in head and calves of legs. 5 P.M.: Temp., 99°; pulse, 80; resp., 28.

October 15th.—Temp., 97°; pulse, 64; resp., 20.
SUCCESSFUL AMPUTATION AT HIP-JOINT FOR ENORMOUS ENCHONDROMA OF THE FEMUR.

By H. W. Carpenter, M.D.,
Ozida, N. Y.

It may be of interest to some of the many readers of The Medical Record, if I give a brief report of an interesting case of enchondroma of the femur which I had nearly two years since. The points of interest are the immense size of the growth and its successful removal.

Druitt mentions a case in which the tumor, after five years' growth, measured three feet in circumference.

My patient was an American by birth, a man aged forty, single. The family history dating from grand-parents showed a decidedly scrofulous taint. His habits of life were good, and till he was nearly thirty-two years of age he was a very industrious man, his work being mostly out of doors.

The history of the tumor dates back nearly ten years ago, to an injury received to the left thigh, while attempting to stop a runaway team. From this time the thigh began to enlarge, the growth being very gradual and accompanied with but little pain, incoincinencing the patient only by its size. It resisted all treatment, and patient became greatly emaciated and feeble; as a last resort he finally consented to amputation at the hip-joint. Accordingly, on January 29, 1882, with the assistance of Dr. Cragni, of the Ozida Community, and Drs. Lewis and Wilson, of Vernon, the operation was performed.

The tumor being so near the body, it was with great difficulty that I cut down and ligated the femoral artery, which I succeeded in doing just below Poupart's ligament. I also ligated the femoral vein to prevent the recurrent hemorrhage. A very short anterior flap was then made; the head of femur disarticulated, and a long posterior flap obtained; these flaps, being abundant to cover the stump nicely, were brought together and secured by stitches, adhesive plaster, and bandage.

Carbolic acid was not used during the operation, neither was a drainage-tube used in the dressing.

The subsequent dressing consisted in frequently washing the stump, and injecting into the wound a one to forty solution of carbolic acid.

On the ninth day the ligation came away from the artery. The flaps united nicely, and the stump was entirely healed in about five weeks after amputation. The patient improved rapidly in health and strength, and was able to walk about with crutches.

The tumor—shown in the cut—one week after the amputation weighed 94½ pounds, and the patient weighed but 85 pounds.

In May of the same year, nearly four months after the operation, the patient took a severe cold which resulted in pneumonia of right lung. There was purulent inflation, and death soon followed.

The principal points of interest in this case are: 1, the possibility of such a growth as a consequence of the scrofulous diathesis; 2, the immense size of the tumor; 3, the rapidity with which the stump healed; and 4, the comfort of and the improvement in the patient after its removal.

Madison County, N. Y.

The New York Veterinary Medical Association met January 4th at Cooper Institute and elected officers for 1884. Dr. R. W. Finlay was chosen President, Dr. L. V. Plageman First Vice-President, Dr. Ralph Ogle Second Vice-President, and Dr. B. C. Cattanach Third Vice-President; Dr. William D. Middleton, of Newburg, Treasurer; Dr. H. Holloway Recording Secretary, and Dr. John W. Jacobus Corresponding Secretary. Articles of incorporation have been filed with the Secretary of State and the County Clerk.

Of the 400 cases there were: Males, 295; females, 105; total, 400. Ratio between males and females 5 to 3.

This completes the enumeration of the histories of the cases, serving as material for the various statistics which follow.
cases of rheumatism in different months of the year is
given in Tables C and E. In these the comparison is
based on the commencement of the joint symptoms, as
learned from the history of the patient.

From these tables it appears that the greatest average
number of cases occurred in May and April, the months
in which the weather is very changeable, and often in-
clement, and notably unfavorable for persons subject to
attacks of rheumatism.

In August and September the minimum number of
cases occurred, while the average number increased from
the latter month to November, when it continued about the
same until April, when the maximum number occurred.

Comparing the average number of cases for each of the
four summer months with that for each of the remaining
months of the year, we get the ratio of 2.124 to 3.402, or
approxim: 2:3 to 5. This is arrived at as follows :

**Table F.** —Comparison of average number of cases

**Antiseptic Surgery at Bellevue Hos-
pital.**

By Robert T. Morris, M.D.,

*New York.*

Whether a surgeon believe in the germ theory or not, it is a matter of little practical importance; but certain facts which are pertinent to the subject of germ development must be accepted by all. The discharges from wounds contain nutritious material for bacteria of different forms, and these bacteria rapidly avail themselves of the opportunity to propagate their kind whenever they are not prevented from doing so. The products of the decomposition caused by their growth are irritating to a wound, and change the natural order of reparative pro-
cesses, to say nothing of the probability that special bac-
teria provoke particular forms of inflammation.

Any one can see bacteria who will take the trouble to look at them, and any one can appreciate the harmful influence of their presence in a wound if he will compare a wound containing many of them with a wound in which few have been allowed to enter. We are pos-
sessed of the means for restraining the development of bacteria, and whoever fails to gain this end fails to avail himself of the proper opportunities for making an ag-
gression against the entrance of bacteria into a wound.

If the surgeon be perfectly familiar with the nature of fermentation processes, it is still no easy matter for him to take the necessary precautions for preventing them, and the most rigid following-out of the technique in his methods is required to insure success. Success is sure to follow strict antiseptic precautions, but it must be re-
membered that bacteria will crawl into the spigot if the bung alone be stopped.

Probably no better place than Bellevue Hospital can be found for comparing the benefits of antiseptic measures with the results of ordinary wound treatment, and in the wards where the details for keeping wounds in an aseptic condition have been carefully studied most grat-
ying results have been obtained. It is a damming thing for very bad compound fractures and the largest of operation wounds to heal under one or two dressings, and such dressings remain perfectly sweet for three or four weeks at a time, so that there is no necessity for the surgeon disturbing them in any way. The patient, instead of having his wounds dressed every day to which protruding suppurating bone, rigidized gauges, or strength, quietly reads his paper and peacefully chews his tobacco while the surgeon passes through the ward and glances at the temperature chart at the head of the bed. In the wards in question pyemia and septicaemia are unheard of, diseases, and foul, purulent wounds are entirely out of date. Primary union is by far the commonest method of repair, and in granulating wounds the discharge is so small in quantity that it seldom appears through the per-
manent dressings.

Various methods and different kinds of antiseptic dressings are employed in the different divisions, but the commonest antiseptic solutions are of carbolic acid, bi-
chloride of mercury, salicylic and boracic acids. Iodide of
formaldehyde is in constant use. Carbolized gauze, borated cotton, or prepared peat, form the larger part of the bulky dressings. Ligatures are carefully prepared before being used, and so are drainage-tubes and protection silk. The
solutions of carbolic acid are aqueous ones, and in the proportions of one part to twenty, one part to thirty, or one part to forty of water. Bichloride of mercury is di-
luted with from one thousand to two thousand five times of water. Salicylic and boracic acids are usually combined in the proportion of one part of the former to six parts of the latter, and these are dissolved in five hundred parts of water. In some of the wards the orders and nurses are given written directions, and the following is a proof of these:

"I. No one shall touch a wound, or the vicinity of a

wound, unless his hands are thoroughly carbolized.

*(To be continued.)*
II. No material shall be allowed to touch a wound, or the vicinity of a wound, unless it has been antiseptically prepared.

III. No sponge shall be employed about a wound unless the sponge has been antiseptically prepared.

IV. No prepared sponge shall be used after it has come in contact with any substance which has not been rendered aseptic.

V. Sponges are not to be touched by any person whose hands are not carbolized.

VI. Sponges employed are not to be used at more than one operation.

VII. During an operation sponges that are bloody are to be washed in a solution of carbolic acid (1 to 40), and by a person whose hands are carbolized.

VIII. Protective silk and rubber drainage-tubes are to be kept in bottles filled with carbolic acid solution (1 to 40), and these articles are to be removed by the senior or junior assistants only.

IX. All material for dressings is to be kept in a perfectly clean place, and the material shall be handled only by carbolized hands.

X. Dressings are to be made up by such persons only as have carbolized hands.

XI. Dressings are to be prepared on clean towels and must not touch surrounding objects.

XII. Instruments are to be kept in carbolic acid solution during an operation, and are to be handled by aseptic hands only."

In giving a description of the routine which would be followed in an operation, it is perhaps best to select some particular case. Let us suppose, for instance, that a man who has suffered a compound fracture of the patella has just been brought in. The patient having been undressed is placed upon a table, which is covered with a rubber blanket and which slopes downward from the end where his head lies. The blanket is gathered at the lower end of the table so that irrigating fluids may run into a pail placed for their reception. Above the table is suspended a large pail which contains any one of the antiseptic solutions which the surgeon may prefer, and descending from it is a long rubber tube supplied with a sprinkling nozzle and stopcock. The injured knee is now scrubbed with soap and the hair in the vicinity is shaved to the scalp or razor. The knee and the leg above and below are washed with a strong carbolic acid solution, and towels which have been wet with the same are placed in every direction about the limb, leaving exposed only that portion which immediately concerns the operator. One assistant is to share the work of the operating surgeon, another handles instruments, and another manages the irrigating solution. The sponges which are being used by the surgeons, and all parties, with the exception of the one who gives the anaesthetic, have rendered their hands aseptic. The operator now makes an incision which opens up the knee-joint widely and exposes the fragments of the patella. The fluid from the irrigator is thrown in jets over the wound, and all clots are washed away. Bleeding vessels are attended to, and the fragments of bone trimmed so that they be readily approximated, and at frequent intervals the irrigator is made to play over the exposed parts. The patella having been firmly wired with strong silver wire, the soft parts are brought into place and sutured with catgut, each structure being separately secured. A drainage-tube has been inserted through a counter-opening at the most dependent part of the synovial sac, and everything is ready for the dressings. Iodoform is first sprinkled over the wound, and then strips of protective silk are laid upon the sutured line of incision. Wads of loose carbolized gauze are placed about the knee to allow of free percolation of discharges, and over all a bulky dressing of borated cotton between layers of carbolized gauze, is bandaged with a carbolized roller bandage. Any splint which the surgeon may prefer is then applied, and the patient placed in bed. If serum appears through the dressings afterward, iodoform is sprinkled over the part and an additional wad of borated cotton bandaged on. Should the surgeon wish to change the dressing an irrigator is employed for sprinkling the knee while this is being done. If absorbable drainage-tubes have been used the dressings will probably not be changed for several weeks; but if the drainage-tubes are of rubber they would be removed at the end of ten days. A patient treated in the manner described would probably not have at any time a temperature much above normal, and it is a common thing for all of the vital signs to remain normal after the first day or two. In case the temperature should run up to 104°F., a change of dressings and a purge would be indicated.

After the patient has remained quiet long enough for reparative processes to be completed the dressings are removed, and the surgeon has only to begin passive motion for the completion of his restorative measures.

TWO CASES OF EMPYEMA IN CHILDREN, ILLUSTRATING RECOVERY BY ABSORPTION AND CURE AFTER INCISION.

By GEORGE M. EDEBOHLS, A.M., M.D.,
NEW YORK.

CASE I.—Willie B., aged two years and six months, was first seen on October 8, 1882, and the following history obtained from the parents: Eleven days before, on September 28th, the child was taken sick and had since been treated by another physician for pneumonia. Severe cough, high fever, with very rapid and labored breathing, constituted the chief symptoms, constant from the beginning to the present moment of illness. Pulmonary examination revealed marked dulness on percussion and bronchial breathing over the right upper lobe anteriorly and posteriorly, and abundant crepitant and subcutaneous rales with slight dulness on percussion over the posterior surface of the right lower lobe. Left lung normal. Temperature, 104°F.

On the following morning apyrexia was established, and the little patient, although exceedingly weak and exhausted, looked comfortable. My attention was now drawn to a swelling of the right side of the abdomen. The parents had first noticed three days previously, on October 6th. The swelling occupied the right knee-joint, which it distended, especially on its inner aspect, and gave distinct fluctuation. It grew steadily in size until October 11th, when the needle of a hypodermic syringe was introduced and a diagnostic sufficiency of pus withdrawn. Removal of the hypodermic syringe had been followed by loss of 2 quarts, and the swelling had, in the meanwhile, been progressing favorably, and on October 13th, with the assent and assistance of Dr. N. G. McMaster, the pyrhythmia genu was operated upon. Notwithstanding the feeble condition of the child, it was deemed best to administer chloroform. Two incisions were made, one on the inner and the other on the outer aspect of the knee, and six to eight ounces of pus evacuated. The operation was done with strict antiseptic precautions, including the use of the spray; the cavity of the joint thoroughly irrigated by a two per cent. solution of carbolic acid; a drainage-tube drawn through from one incision to the other, left in situ, and the wound dressed antiseptically. No reaction followed the operation, and the dressings were subsequently renewed every fourth or fifth day. The drainage-tube was cut in the centre, and each half gradually withdrawn from the corresponding opening at succeeding dressings. A month later, on November 6th, all discharge had ceased; on November 13th both wounds were entirely healed, and although the tissues on its anterior surface showed slightly thickened, perfect mobility of the joint obtained.

We retrace our steps in the history of the case to October 16th, when a lobular pneumonia of the left
lung developed, accompanied by slight fever and constitutional symptoms lasting about four days. The disease occupied chiefly that portion of the left lung extending from the second to the fourth rib anteriorly, and there the foci of bronchial breathing were most numerous. Over the lung the consolidation and reduction of breath sounds was observed until October 28th, when the child complained of pain in the left side, and slight dyspnea was noticed which kept on gradually increasing. On November 2d the pleura was discovered to be filling with fluid. There was dulness, almost flatness, on percussion over the lower portion of the left lung, both anteriorly and posteriorly, excepting a small belt, about an inch in width, encircling the lowest portions of lung, from the precordial space in front to the spine behind, over which normal resonance and vesicular respiration could be obtained. Over the dull and flat portions breathing was either distant bronchial or entirely suppressed. The children was dispelled to the right of the sternum, and this was taken as an indication of the presence of a considerable amount of fluid in the left pleura. Repeated blisters, diuretics, diaphoretics, and cathartics exerted no appreciable influence in checking the steady rise in the level of the fluid. The dyspnea, however, did not grow extreme until about November 18th, when it became so severe that the patient's life seemed in constant imminent peril.

On November 25th the child was taken to Dr. John H. Ripley, at the Polyclinic. The following memoranda of his condition were recorded, and a copy thereof kindly furnished me by Dr. Ripley:

**Inspection.**—Falling in of intercostal spaces and epigastrium during inspiration.

**Palpation.**—Heart apex under right nipple. On right side vocal fremitus feeble, and on left generally absent, except in front under clavicle, where it is a little more marked than normal.

**Percussion.**—On left side absolute flatness over upper third of lung; below, tympanitic, due in part to stomach and in part to dilatation of cardiac space. On right side percussion varies; over certain portions exaggerated—vesiculo-tympanitic—and over others dull.

**Auscultation.**—Left lung: in front, at apex, bronchial respiration with diminished vocal resonance; behind, at apex, broncho-vesicular respiration; at extreme apex and over remaining upper third, distant bronchial breathing; over lower two-thirds, absence of vesicular murmur, with sonorous and creaking sibilant râles. Right lung: exaggerated breathing, with large dry and moist râles.

An encapsulated pleuritic effusion was diagnosed and, with a view of determining the character of the fluid, a hypodermic syringe was introduced in the fifth or sixth left intercostal space posteriorly, and a small quantity of pus withdrawn. The indication for its evacuation seemed evident and urgent enough, and, with the father's assent, free incision was determined upon. On reaching the home of the patient on the following morning with Dr. Ripley, we found that the non-consenting and alarmed mother had fled with the child to parts unknown. After a second unsuccessful attempt, made a few days later, to find the child at home, the operation was of necessity abandoned and further attendance discontinued. A speedy dissolution ensued at this time the fate almost inevitably in store for the little sufferer. Food had been refused and no sleep obtained for many successive days, that with the time and patient rendering any approximation to the recumbent position impossible.

In the latter days of April, 1883, I was summoned to attend the mother of the child, and to my surprise found the latter alive, running about and playing with other children, apparently as well as most of them. The latter informed me that since November 28, 1883, the date of my last visit, the dyspnea had greatly grown less and less, and since the beginning of February the child had had neither cough nor dyspnea, and was about as well as ever. At no time had the cough, generally dry in character, been at all violent, and there had never been anything like abundant expectoration. On examination of the chest I found normal resonance on percussion and vesicular respiration over entire right lung; vesicular, though feeble, respiratory murmur and slight diminished resonance over entire left lung; no râles. The cardiac apex beat in the fifth intercostal space, midway between the edge of the sternum and the left nipple. The right knee had given no further trouble, the incisions had remained healed, and pus had not reaccumulated. There was not the slightest impairment of its function in any direction.

I communicated the facts as above stated to Dr. Ripley, and invited him to verify them for himself by a visit to the patient. The doctor stated at the time that although absorption of a purulent pleuritic exudation by the unaided efforts of nature was of infrequent occurrence, it is not until a reabsorption has taken place, however phthisis usually developed subsequently in these cases, and that he should not be surprised if such should be the result in the present instance.

For one reason or another it was not until October 19, 1883, that we again saw the child together. I had, in the meantime, with a view to watching the progress of the case, visited the patient on several occasions alone. In August, 1883, cough, after an absence of nearly four months, returned; slight at first, but gradually increasing in amount. A few crepitant and subcrepitant râles were recognized in the left upper lobe, and the percussion note over the same region grew less and less resonant. In September a chronic catarhal pneumonia appeared in the left upper lobe, causing only a small degree of fever, and the percussion diminished in the left upper lobe. In the beginning of October the physical signs demonstrated the existence of a cavity near the left apex. On October 19th, as above stated, Dr. Ripley visited the case with me and the following status praebens was recorded:

Circumference of chest immediately below nipples, 39½ inches; right side, 35½ inches; left side, 35 inches; apex beat in fifth intercostal space, 1½ inch to left of median line and 1½ inch to right of left nipple.

Right lung: Percussion note and respiratory murmur exaggerated anteriorly; posteriorly, exaggerated respiratory murmur—rude, and with a few subcrepitant râles, at apex.

Left lung, anteriorly: Percussion note dull, tympanitic under left clavicle down to nipple; from nipple down quite dull. Cavernous breathing and loss of respiratory murmur under clavicle. Mucous and creaking sibilant râles down to nipple; below that respiratory murmur very feeble.

Left lung, posteriorly: Percussion note very dull from apex to lower lower angle of scapula; from latter point down, rather exaggerated. Over entire upper third of lung respiratory murmur for the most part bronchial, with mucous and sibilant râles. Over lower one third respiratory murmur somewhat feeble, but otherwise normal. Cavernous breathing at superior internal angle of scapula.

The history of the main events in the above case may be summarized as follows:

The acute catarhal pneumonia of the right lung began September 28, 1883, and involved the entire upper and posterior portions of the lower lobe. The acute symptoms due to it terminated on October 9th, and on October 10th complete removal of the products of inflammation was indicated by the physical signs.

The pyaemia gnos first attracted attention on Octo-
ber 6, 1882. On October 11th the presence of pus was demonstrated; the operation was performed on October 13th. A month later the wounds had healed and the function of the joint was perfectly re-established. The lobular pneumonia of the left lung developed about October 16, 1882. The auscultatory signs still showed its presence to a slight extent on October 28th, when the pleuritis supervened.

The pleurisy of the left side began, as just stated, on October 28th. It involved the pleura overlying those portions of lung previously the seat of catarrhal pneumonia. The resulting inflammatory products subsequently became encapsulated in this situation, leaving a small zone above and below where the lung reached to the chest-wall, to which it was probably bound by adhesions. On November 25th the fluid was demonstrated by the hypodermic needle to be purulent in character, and was sufficient in quantity to crowd the heart over to the right nipple. About this time, to judge from the further history as obtained from the mother, resorption of the pus began, and in April, 1883, and at frequent examinations subsequently, I could find no evidence of the presence of fluid in either pleura. Careful inquiry failed to elicit the exact period of this resorption. It was due, probably, to the possible evacuation of pus through the bronchi. At this time, moreover, the lungs themselves seemed to be free from disease. In August, 1883, a catarrhal condition established itself in the upper lobe of the left lung and gradually led to destruction of pulmonary tissue and the formation of a cavity.

Case II. Joseph P., aged two years and ten months, in November, 1881, had an attack of acute catarrhal pneumonia of the right upper lobe, for which I attended him, and from which he made an excellent recovery. With this exception he had been well up to November 26, 1882. On that day, at 9 a.m., he was taken with a slight paroxysm of cough, which I considered due to effusion of fluid into the bronchi. I saw him at 11 a.m., which his temperature was 104.2° and pulmonary examination gave negative results. On the following morning I coughed in addition to the continued high fever. Dulness on percussion, loud bronchial breathing, increased vocal fremitus and resonance were found over the lower lobe of the left lung. On November 31st the dulness had changed to complete flatness; the breathing was faintly and distantly bronchial; vocal fremitus and resonance were still reduced, and the physical signs of the pneumonia were marked by those of the accompanying pleuritis. During these three days the temperature remained constantly at 104.2° to 104.8° F.

On December 1st there was sudden approximate defervescence, the thermometer in the rectum indicating 100.4°. The physical signs remained the same. From December 1st to December 7th, the temperature varied between 101.4° to 102.5°. The slight rise appeared to be due to an extension of the catarrhal pneumonia to a portion of the left upper lobe. On December 7th and the three days following, the temperature did not rise above 99.2° in the rectum. On December 11th the needle of a hypodermic syringe was introduced into the sixth intercostal space of the left side posteriorly, and a syringeful of sero-purulent fluid withdrawn from the left pleura. The child continued experiencing slight febrile movement and not doing particularly well until December 22d, when another puncture demonstrated a change in the character of the fluid to thickly purulent. The amount of fluid was sufficient to place the cardiac apex beat to within an inch of the right nipple. The dyspnoea was proportionate. Thoracectomy was advised and was being debated by the parents, when, on December 26th, the patient was taken with measles contracted from an elder brother. With the exception of a rather severe bronchitis, the disease ran a mild course. On January 6, 1883, with the assistance of Dr. N. G. McMaster, a free incision was made in the seventh intercostal space immediately below the angle of the scapula. About a pint of thick, laudable pus was evacuated. The operation was done under the spray, a drainage-tube introduced, and the pleura syringed out with one per cent. solution of carbolic acid. The tube was held in place by a string attached to it and tied around the chest. Gutta-percha protective, salicylated jute and carbonized gauze bandages completed the dressing.

On the following day the pleura was again irrigated by a one per cent. solution ac. carbol., until the fluid returned clear. Thereafter the dressings were changed about once in three or four days until final removal of the tube, on March 18, 1883. A few days later the wound was entirely closed and has remained so until the present time. Immediate and striking improvement in the child's condition followed the operation. He ate and slept well, and was permitted to run about the room with his companions. His temperature fell to normal and remained thus until the final closing of the wound, with but little fluctuation. The discharge was still present due to clogging of the tube and consequent impediment to the free discharge of pus. The removal of this condition of affairs was followed by prompt defervescence.

Vesicular respiration and nearly normal resonance on percussion were re-established over the entire left lung, and the child is to-day enjoying the best of health. The chest has fully expanded, and we have for the remaining scar, there would be nothing to indicate to the eye on which side the disease had existed. The heart has returned to its normal position; a faint, soft, systolic bruit, however, is heard at and near the apex. Careful menuration of the chest shows both sides to be equal, each measuring ten inches in circumference. The statements and measurements were all verified by Dr. John H. Ripley, who kindly visited the ex-patient with me on October 19, 1883.

In connection with the etiology of the case, the following facts may be of possible interest. A brother of our patient, aged five years and three months, was taken with acute pneumonia of the right lower lobe and its overlying pleura, on November 24, 1882. The symptoms were very severe, the temperature remaining between 104.2° and 105.0° for five days. Defervescence occurred on November 30, 1882; a week later complete absorption of the pleuritic fluid had taken place, and the boy was turned out of the house. On December 14, 1882, he was suddenly taken with acute pneumonia of the right lower lobe and inflammation of its overlying pleura. Defervescence, as in the first attack, set in six days later, on December 20th. Our own patient was taken ill on November 28th, and appendix in his case was established on the fourth day. Here were three attacks of acute pleuro-pneumonia occurring within three weeks in two members of a family of four boys; all were characterized by extreme constitutional symptoms, and in each there was a considerable amount of pleuritic exudation. In the elder child's case this was, in both instances, speedily resorbed; in our patient it became converted into pus.

The case of Willie B. — proves positively the possibility of the resorption of a large quantity of a thickly purulent pleuritic exudation. Conversation with a number of brother practitioners has left me with the impression that such possibility is a fact not so universally recognized as it should be. That some difference of opinion on this subject exists also among writers on diseases of children, the following quotations will, I think, serve to show:

Hillier: Pus left in the pleura may be enclosed in a dense pyogenic membrane, the fluid portion becoming absorbed.

West: The fluid very speedily becomes purulent, and
correspondently inapt for absorption, though by no means incapable, as was once imagined, of being absorbed. The inactivity of the absorption of pus is indeed no longer disputed, but at the same time pus is inapt to be absorbed, and its absorption is sure to be tedious.

Steiner: Purulent effusion, whether free in the cavity or asciliated, may become absorbed.

I. Louis Smith ("Diseases of Infancy and Childhood," fourth edition, 1879): In empyema the patient cannot recover by absorption of the pus unless its quantity is small. If the pus is in such quantity as to be apparent to the naked eye, recovery is slow and uncertain, and usually impossible. Suppurative pleuritis or empyema is in time fatal unless the pus is evacuated.

W. H. Day: An empyema when left to itself may dry up and disappear by absorption.

Vigil, in a matter-of-fact way, speaks of the absorption of a purulent pleuritic exudation as of relatively frequent occurrence.

Meigs and Pepper ("Diseases of Children," fifth edition, 1893): under the treatment of the patients (of empyema) the most favorable result that can be hoped for is that the pus will either evacuate itself externally, or open into the lung and be expectorated.

Condle ("Diseases of Children," fourth edition, 1853): Extensive effusion will often be entirely absorbed if it consists chiefly of serum; but when purulent, it sooner or later causes death of the patient.

It being thus established that even a large accumulation of pus in the pleural cavity may be removed by absorption by the unaided efforts of nature, the question arises whether such a result is the most desirable one under the circumstances. Taking into account the length of time which must necessarily elapse before full evacuation is obtained, and the risk of the disease being repeated, and the increased liability to permanent pathological changes to which it is exposed in a state of compression, I consider the indication plain to restore the normal relation of the parts concerned as speedily as possible. I think the result in Willie B.—s case would have been a more satisfactory one, and that his chances of escaping phthisis would have been fair, had evacuation been practiced. That the pleural abscess would have behaved kindly after operation may be inferred from the readiness with which the pyarthrosis germ healed under such disadvantageous circumstances.

Dr. Joseph Schnetter, of this city, related to me in connection with the death of the patient, the cases of empyema in children, occurring in his practice, in which after a single evacuation of the pus by the aspirator, the patients progressed to full recovery. Authors are at present agreed as to the propriety of paracentesis thoracis in cases of purulent pleuritic effusions, and I think I would, in my next case, first aspirate the thorax, and if the fluid, after the operation, reaccumulated, I should then proceed to free incision. West dreads the drain following free incision, preferring on that account repeated paracentesis. This objection is obviated by the employment of the antiseptic system. In the case of Joseph P.—, I should estimate the quantity of pus lost from the second dressing, on the day following the operation, until final closing up of the wound, at certainly not more than six ounces.

The dry mouth of the lithotomist.—At a recent clinic, Prof. Brinton said that an attendant of lithotomy is dryness of the surgeon's mouth, similar to that produced by belladonna; and Prof. S. D. Gross remarked: "It is peculiar to the operation for stone; I have often felt it." A thesis showing the relation of a stone in one man's bladder to the salivary glands of another man would probably take the Lea prize.—Col. and Clinical Record.
favorable action of turpentine sprays upon chronic catarrh with swelling of the mucous membrane and the resorption of chronic exudations. It may also be assumed that when given internally it assists the action of the drugs.

Apopomoria, pilocarpine, and emetine cause considerable increase of the mucous secretion. In experiments upon dogs and cats crepitant râles were heard over the lungs. The tracheal mucous membrane was always swollen, the superficial scarring showing a granular condition. Section of the laryngo-tracheal nerves did not hinder the increased secretion. These drugs are indicated, then, in catarrh. Pilocarpine, which causes secretory troubles in the whole living structure, must be used with caution. Atropine causes a great deal of dryness in the tracheal mucous membrane; the secretion being completely checked in the course of forty or fifty minutes, while the mucous membrane is hyperemic. The same characteristic dryness is produced after section of the laryngo-tracheal nerves.

It is evident, therefore, that the action of atropine is exerted upon the mucous-forming cells and upon the terminal nerve-filaments which preside over the mucous secretion. Hence it appears that the action of atropine on catarrhal conditions is not due to its anesthetic properties, but to its action on the secretion of mucus. Morphia decreases the mucous secretion to a slight degree and diminishes reflex irritability. Morphia and atropia, applied at the same time, produce their special actions, and their combined use is indicated in troublesome catarrhal conditions with much secretion.

The Treatment of Volvulus.—When there is intestinal obstruction due to twisting of the sigmoid flexure, its reduction is readily effected after abdominal section, but it sometimes happens that the intestine becomes again twisted after the operation, and is then at once obstructed. W. Runge, in an article in the Centralblatt für Chirurgie of October 27, 1873, advises that the colon be fastened by sutures to the abdominal wall. Several sutures must be used, passing through the mesentery on one side and the peritoneum of the left abdominal wall on the other, in such a way that the upper part of the flexure, which seems to be the most movable, shall be kept slightly raised. In the same way the mesocolon might be fastened up after the reduction of an intussusception by means of laparotomy, when a return of the invagination was to be feared.

Disadvantages of Kairine in Pneumonia.—Dr. Riegel advises against the employment of kairine in pneumonia. Independently of the fact that the danger in pneumonia does not lie in the high temperature, the antipyretic effect of the drug in this disease is very slight. It was not always possible to reduce the temperature to the normal even with doses of kairine, and when this result was obtained the fever would often return quickly in spite of a continued administration of the remedy. The influence upon the frequency of the pulse was still less marked. The chief inconvenience of the kairine treatment, however, lies in the fact that it often causes a most threatening state of collapse, and it was an occurrence of this kind that induced the author to desist from any further employment of the drug. Centralblatt für Klinische Medicin, November 10, 1883.

The Relation between Edema and Disease of the Kidney.—One of the chief grounds upon which Cohnheim rejected the theory of the hydric nature of anaasara in acute nephritis was that he had never succeeded in producing it in dogs after the artificial production of very marked hydremia. Dr. Gärtnner has, however, obtained different results upon repeating these experiments. He found edema of the skin after the slow injection of a solution of common salt. He used an excessive quantity of the solution. In one case, in which the dog weighed about 65 ounces, he injected in the course of four hours 62 ounces of the saline solution.—Centralblatt für Klinische Medicin, October 13, 1883.

Medicated Injections into the Uterine Tissues.—Dr. Schäcking makes injections into the uterine substance by means of a syringe similar to the ordinary hypodermic syringe, only with a much longer needle, so that the point may be inserted into the neck of the womb through an ordinary cylindrical speculum. He has in this way obtained invasions of atropine and Fowler's solution in the case of uterine fibroids, and in subinvolution of the uterus. In hyperplasia of the neck and hypertrophy of the cervical glands he uses tincture of iodine. Injections of a mixture of tincture of iodine, Fowler's solution, and carbolic acid have been employed to combat inflammation of the uterus.—Bulletin Général de Thérapeutique, October 30, 1883.

Fracture of the Skull by Contre-coup in the Fœtus.—This accident has been hitherto regarded as impossible, owing to the peculiar formation of the cranium of the newborn. Dr. Pericle Sacchi has, however, recently made some experiments (Journal de Médecine de Paris, November 17, 1883) which go to prove that fracture of the skull may, under certain conditions, be produced by contre-coup in the foetus.

Icterus During Pregnancy.—At a recent meeting of the Académie de Médecine, Dr. Queirel presented a communication upon the etiology of jaundice occurring during pregnancy. He mentioned three varieties: 1. That occurring at the beginning of pregnancy, and dependent upon a morbid state of the alimentary canal; 2. Icterus occurring toward the end of pregnancy, due to compression of the excretory ducts; 3. Jaundice met with at any period of pregnancy depending upon disease of the liver itself.—Gazette des Hopitaux, November 22, 1883.

Iron in the Treatment of Skin Diseases.—Dr. Casarini has employed the perchloride of iron with advantage in a large number of chronic skin affections. He uses an ointment of from one to three grains of perchloride of iron, with one grain of laurina, and with the addition from a number of observations that: 1. Perchloride of iron (internally administered) is the most efficacious agent in the treatment of simple or hemorrhagic purpura; 2, it is very useful to combat the anemia which often accompanies certain cutaneous affections, such as rupia, ecchyma, and impetigo; 3, its external application gives excellent and speedy results in cases of scrofulous and syphilitic origin; 4, in the form of ointment it constitutes a good remedy in the squamous skin diseases, especially in psoriasis.—Journal de Médecine de Paris, November 24, 1883.

Glycerine in FEVERS.—Dr. Mariano Semmola opposes the exhibition of the salicylates, phenic acid, or alcohol in acute pyretic conditions, admitting the latter only in cases of great depression or threatening paralysis of the heart. He thinks that he has found in glycerine a substance which may be advantageously substituted for these remedies. The following is the formula used by him:

B. Glycerine ........................................... ⅓ i.
Acid citrici aur tartarici .......................... ⅓ ss.
Aq .................................................... ⅔ vi.
M. Sig.—One or two tablespoonfuls every hour.

This mixture tastes good, is readily taken by the usually thirsty patients, and is very well borne. The author employed this remedy in several cases of typhoid fever with very good results. In most of the cases the exhibition of the glycerine was followed by a decrease in the daily excretion of urine varying from ninety to one hundred and fifty grains.—Allgemeine Medicinische Central-Zeitung, December 1, 1883.
UNSATISFACTORY MEDICAL SERVICE ON TRANSATLANTIC STEAMERS.

During the past two years the unsatisfactory medical service on transatlantic steamers has received much attention from the British press, and has formed the subject of strong resolutions by prominent English societies. The British Medical Association, which appears to have thoroughly investigated the subject, has presented a memorial to the President of the English Board of Trade, which "respectfully sheweth that the medical and sanitary administration of ocean steamers, especially of those engaged in the North Atlantic emigrant trade, is often seriously defective, whereby many lives are annually sacrificed." And more recently a deputation from the Association, supported by several well-known Members of Parliament, interviewed the same functionary, with no more encouraging result than an indefinite promise that the subject would be remembered in the coming shipping bill.

Our British contemporaries remind us that it is we who are most interested in this matter, that the battle they fight is mainly for the health interest of our citizens as opposed to the money interests of their own, and that we should be up and doing on our own behalf. Nor shall we be slow to take the hint. In another column we publish a letter from Dr. J. A. Irwin, who has been the leader of the movement in England, and who seems to be convinced that pressure from Washington may be required to enforce necessary reforms upon unsympathetic ship-owners. Statistics show a high mortality upon Atlantic steamers. Dr. T. Turner's ten years' report of vessels entering New York, proves a death-rate more than double that ordinarily occurring in our great cities; and English Parliamentary returns admit a mortality far exceeding the necessities of transit. And this among persons enjoying exceptionally high vital conditions.

If, as there seems every reason to believe, a part of this excessive mortality, or of the concomitant health depression, may be attributed to inadequate medical arrangements and inefficient sanitary administration on ship-board, then the ship-doctor grievance merges into a question of first importance to the nation, and should without delay become the subject of sweeping legislation by Congress. It is certain that the present system is rotten in principle, and often disastrous in results. The ship-surgeon is appointed, not by any responsible authority in the interest of the passengers, but by the owners of the ship, who have no practical concern in his competency, and who select him, we are informed, "with little regard to age, experience, qualification, or character."

As a matter of fact, of 135 different medical officers who during the first six months of 1882 had full medical charge of 104 British steamers, carrying emigrants to this country, no less than 54 would have been ineligible through lack of the minimum professional qualification for the most junior medical appointment in the English navy, army, poor-law, prison, or asylum services; and but 27 of the entire number possessing any qualification as physician and surgeon had reached their thirtieth year.

And it should not be supposed that because our English friends have insisted upon the publication of official reports, the British steamers are necessarily worse than their competitors in these respects. On the contrary, judging by results, British vessels stand first upon the list. When the ship-surgeon, thus appointed, enters upon his duties he finds himself surrounded by insurmountable difficulties.

The hospitals are generally insufficient, often ill-constructed, and are not unfrequently taken from his control and devoted to other purposes than the accommodation of the sick. He is allotted quarters without regard to his health, personal comfort, or the possibility of efficiently discharging his professional duties. Let a single example suffice: On the latest addition to a splendid fleet, carrying annually its thousands upon thousands, the surgeon's room measures five feet eleven inches by five feet-three inches, is without any window or port-hole, and is situated below in a narrow thwart-ship passage, the door being opposite to and within thirty inches of the passengers' water-closets. The surgeon is denied authoritative control in even the most purely sanitary matters. He is allowed no assistance, no dispenser, no hospital nurse, and no servant; and thus in the early days of bad weather and general sickness he finds himself face to face with duties so numerous and so heterogeneous that no person could possibly perform them satisfactorily. His salary never exceeds fifty dollars per month.

All this may have been tolerable so long as the position of ship-surgeon was really a sinecure, demanding no special qualification and offering advantages to those who, from delicate health or otherwise, desired sea-travel. It is evident, however, that the medical charge of fifteen hundred or two thousand passengers, under all the hazardous circumstances of the transatlantic voyage, is an onerous and important duty, requiring all the qualities deemed necessary in a high-class public official, together with a thorough knowledge of all branches of medicine; and that valuable lives should be risked to save the ship-owners the cost of suitable sanitary arrangements and a competent physician is absolutely monstrous.

Dr. Irwin suggests the example of the British Colonial Government, who, it appears, insist upon appointing their own medical superintendent to every vessel carrying emigrants to the Colony. Something must be done, and there seems to be no legitimate reason why Congress should not enforce the same privilege.
THE COUVEUSE FOUR ENFANTS.

It is now somewhat over two years since M. Tarnier put into practical use his couveuse, or artificial "brooding-hen," for feeble and immature infants. Various and incomplete descriptions of this apparatus and its work have been published, and strange misconceptions of what the couveuse is, and what it is intended to do, have got abroad. It is with much satisfaction, therefore, that we have received a monograph covering fully this subject, by M. A. Auvard, interne at the Maternité de Paris, where the couveuse was first introduced and is now being used. M. Auvard has given, in an intelligent and apparently impartial manner, a description of the construction and mode of use of the couveuse, and the results obtained from it in the hospital.

The couveuse used in the Maternité consists essentially of a wooden box, with double walls, for the purpose of retaining the heat better. This box is 95 cm. long, 70 cm. wide, and 85 cm. high, and rests upon a pedestal. It is divided into two compartments, an upper and a lower, by a horizontal partition. The lower and larger compartment contains a reservoir of metal for holding warm water, the upper compartment contains the cradle for the infant.

The reservoir holds about eighty litres, and is heated by a lamp, or it may be put in connection with a large reservoir and be constantly fed in this way.

The upper compartment is covered by a double movable glass slide. It is in communication with the lower compartment, and also with the outer air. The reservoir being filled with boiling-water, air passes in at the bottom of the box, ascends around the heated reservoir, enters, warmed, to the upper compartment, and passes out through orifices in the top of the couveuse.

In cold weather the water in the reservoir is kept at a boiling temperature for two hours three times a day. This suffices to keep the temperature in the upper compartment, where the infant lies, at about an average of 36° C. (86° F.). This is found to be the best temperature on the whole, although at the beginning of treatment it may be raised to 34° C., or even 35° C. (93°-95° F.).

In Tarnier’s couveuse the heat is not maintained constantly at the same point. Dr. Budin, at La Charité, however, has devised an apparatus by which this object is attained.

Apart from its confinement most of the time in the couveuse, the care of the infant does not differ very much from that ordinarily employed. If practicable, the child is nursed by the mother, during which process it is taken from its hatching-house and exposed to the ordinary air of the ward. It is clothed in the usual manner, and receives a bath daily.

The clinical results obtained by this process of baking babies are naturally the points of main interest. The couveuse is not intended for the cultivation of giants, as has been facetiously suggested; but for preserving and strengthening the vitality of infants born before term, or congenitally feeble; for infants suffering from oedema and cyanosis, respiratory troubles, etc. The total number of cases treated—perhaps we should say, heated—by Tarnier and Auvard is 151, the duration of the "incubation" being from one to forty or more days.

The results can be shown best by the following table:

<table>

The couveuse seems to have been especially efficient in cases where there was imperfect development, as in very small or prematurely born infants. This is well shown by comparative statistics of infants born weighing 2 kilogrammes or less.

Total treated in couveuse, 79; living, 49; dead, 30; mortality per cent., 30. Without couveuse, in Maternité de Cochin, 30; living, 10; dead, 20; mortality per cent., 66. Without couveuse, in Maternité de Paris, 116; living, 40; dead, 76; mortality per cent., 65.

These figures show that the couveuse reduces the mortality in this class nearly one-half, which certainly speaks most eloquently for its usefulness.

M. Auvard has made some studies as to the effect of the new apparatus upon the pulse, respiration and temperature. Of these we can only say in brief that the essential physiological change produced is an increase in the superficial temperature of the infant.

In conclusion, it appears that the couveuse has done enough to establish a claim for its wider trial by the profession. It is undoubtedly superior to the apparatus for prolonged baths devised and used by Winckel. A simpler and smaller couveuse can be made than that used in the Maternité. It is not impossible that the simple use of large cans of hot water in or about the infant's bed may be almost as efficacious as the more elaborate devise of the couveuse.

MEDICAL LEGISLATION IN VIRGINIA.

The Legislature of Virginia is to be urged to pass an anatomy law similar to the one in Pennsylvania, and a bill has been framed and introduced for this purpose. It is expected that by the passage of this bill the robbing of grave stones will be prevented, and that medical students will be provided in a legitimate manner with material for dissection.

A bill is also now before the Virginia Legislature, dealing with the subject of the regulation of the practice of medicine. The bill provides for an Examining Board composed of gentlemen who are nominated by the State Medical Society and appointed by the Governor—or else appointed by the Governor independently. Every person who commences to practise medicine in Virginia after January 1, 1885, will be obliged to be examined by the Board and to register his name in the County Clerk's office.
The bill is apparently a very poor one, and is another product of the present craze for medical registration laws.

The medical profession ought to bear in mind the fact that a law compelling a legal registration of physicians will not be of necessity a benefit to any class but the quacks. Good registration laws are most useful, but bad ones are most pernicious. Registration laws should have as their main object the prevention of quackery and imposture. The proposed Virginia law is very vague in its requirements, and its effect will be apparently to give a legal standing to every one who is now assuming to practise medicine in Virginia.

THE SIMS MEMORIAL FUND.

The proposition for erecting a monument to the late Dr. Sims meets with universal favor. Already substantial proofs of this are manifesting themselves from different parts of the country. The contributions range in amount, thus far, from one dollar to one hundred, and already make a good showing. At the next meeting of the Executive Committee definite plans will be laid for systematizing collections and giving due publicity to the project. The publication of list of subscribers will then be commenced in The Record, and additions thereto published from time to time. In the meanwhile the medical journals throughout this and other countries are invited to aid the Committee in any way that may be deemed advisable. The end in view would be very efficiently met if the editors of such periodicals would kindly consent to appeal to their subscribers, and forward the amounts thus collected to the treasury of the fund. Acknowledgments for the same would be gratefully acknowledged by the Committee. The same invitation is extended to members of the general committee in different States who have opportunities for bringing the matter before the medical and lay public in their different localities. It is not intended that subscriptions should be restricted to members of the profession, but to all former patients of Dr. Sims who may feel that they owe to him a debt of gratitude for skilful services rendered. Already several prominent ladies in this city are interesting themselves in the movement, and the promises are good for large subscriptions through their instrumentality. No restrictions will be placed on them regarding any means they may adopt to secure the end in view, and the aid which they can give the Committee cannot be too highly appreciated. In fact, such testimonials from women would be an earnest of the highest appreciation of the labors of one who devoted his genius to the amelioration of their numerous and distressing ailments.

THE LIMITS OF MEDICAL ADVERTISING.

We regret very much to find that the venerable editor of the Journal of the American Medical Association persists in his advocacy of medical advertising beyond what appears undoubtedly to be safe and proper limits. The points at issue are very simple and are briefly these:—

The Journal in question says:

First, that a doctor can, publish or use a professional card as freely as he likes.

Second, that a doctor can add to his professional card the notice "practice limited to" any particular branch or branches of medicine that he likes.

We venture to protest against this and to assert that, if the physician were inclined to measure his conduct by the letter of the law thus laid down, there would be practically very little limit to the amount of advertising which he could legitimately do. It is useless to talk about what Dr. Davis really means, or what the term a "professional card" usually signifies.

We simply criticise what our contemporary says; and it was in effect this: that a doctor can publish his card in the newspapers as much and as often as he likes, dotting a whole page over with it; and he can even hire a man to stand on the street corner and "distribute the cards as freely as he chooses."

This is the license which our contemporary's words give, and we protest against it. If the editor does not mean it, or if it is one of those typographical errors which the editorial columns of our solecistic contemporary have heretofore been so largely devoted to explaining, very well. Certainly we are very loath to believe that our venerable friend is devoting the last years of his useful life to the authoritative support of the view that physicians may "publish and use their professional cards as they like."

To the second point we also take exception. We are inclined to think that the permission graciously granted by the Association, to allow the words "practice limited to" to be added to the card, is silly rubbish. At the same time, if it means anything, we reiterate that its meaning is very little seared in the lay mind from "practice special." According to Webster, special means "limited in range," in other words "limited," and the novel definition of special, which our contemporary gives as something "unusual or superior," is quite a lexicographical revelation, or perhaps another typographical error. The standard dictionaries at any rate support the view which would be ordinarily taken, that specialists could trade on the suffix "practice limited" as well as on any other.

They do not do it because, as we are glad to believe, doctors are better than their code. And it is quite a gratuitous insult for our contemporary to say that ambitious young specialists would gladly avail themselves of the ethical privilege of announcing themselves on their cards as such.

We can recapitulate the whole matter best perhaps by an illustration. Thus:

DR. SMITH JONES,
No. 4000 warash Avenue, CHICAGO.

Practice limited to venereal diseases and loss of manhood.
Office hours: 9 to 2.

Form of card authorized to be printed, published, distributed, and used as freely as is wished, by the editor of the Journal of the American Medical Association.

In conclusion, we regret that our venerable friend should conclude the extraordinary defence of his awkward and untenable position by descending to disingenuous personalities and misrepresentations.

In its long career The Record has always tried to show that it had the best interests of the profession at
THE MEDICAL RECORD.

A FEW WORDS ABOUT THE INDEX MEDICUS.

An appeal has again been made for the support of the Index Medicus. Most of the medical journals have taken the matter up and have earnestly urged its claims upon the profession.

It is a little strange that a periodical of such reputed value should meet with so little substantial aid. We are of opinion that some judicious criticism is one of the things that it needs even more than the indiscriminate praise which has heretofore been paid to it.

Every one must acknowledge that the Index Medicus represents a vast deal of intelligent and conscientious labor. But it is also true that from another point of view it is a monumental piece of journalistical dulness and bibliographical inutility.

In the first place the Index Medicus need not and should not be published monthly. Now, if a physician wishes to look over the literature of a subject for five years, he must look over sixty different pamphlets. In the time which this occupies he could consult the index to twenty leading medical journals.

The bibliographical appendices of Schmidt's Jahrbücher are published only quarterly, while those of Virchow and Hirsch's Jahresbericht appear semi-annually, as do those of other journals of this class.

The profession does not need a monthly bibliography.

Again, the references in the Index Medicus appear to be ingeniously devised, in order to destroy as much as possible their practical utility. There is no subject-index, properly speaking. If one wishes to look up the subject of the liver, for example, he must go through innumerable monthly volumes, looking under the heads of surgery, medicine, anatomy, physiology, etc. If he is not familiar with French and German, he is still more in trouble. In fact, life is too short for the profitable use of the Index Medicus in very many directions. The large German, English, and French Year-Books publish subject-indices, with which one can, in a very short time, find out all that days of study of our American journal could give.

In fine, then, let the managers of the Index Medicus adopt intelligent methods in the making up of their journal. Let them give the profession an annual or a semi-annual volume with a subject-index. With such changes the Index Medicus will deserve the support of the profession, and, we believe, will get it. As it is now, it is an example of a well-meant but comparatively useless monthly bibliography.

THE HOSPITAL COLLECTIONS.—We are happy to state that since last writing, a week ago, the hospital collections have received much larger additions than we had anticipated. The total sum reported last was $40,082.03. It seems possible now that the amount may equal or exceed the highest previously received. Two hundred and ten churches contributed, against ninety-four last year.

News of the Week.

THE "EPHEMERIS" AND THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.—Our esteemed contemporary the Ephemeris, in its last editorial item in the number for January, 1884, unintentionally makes a misstatement concerning the Medical Society of the County of New York. It says: "At the next succeeding meeting the addresses of the retiring president and the new president were made, and other matters of interest were on hand, but the meeting was not so large. Just about sixteen persons were present, and of these four were reporters, the two presidents making two others of the sixteen."

In the above quotation reference is made to the adjourned annual meeting with the stated meeting held November 26, 1883. If the writer of the article, which also contains an uncalled-for slur, had taken pains to obtain reliable information concerning the number of persons present at those meetings he would have had the pleasure of learning that sixty instead of sixteen were in attendance. It is also worthy of note that at the stated meeting of that evening fifteen new members were elected, and that certificates of membership were presented to twenty members, all helping to swell the "sixteen."

Dr. M. M. Lewis, a prominent physician of Alexandria, Va., died on January 20th at the age of fifty-nine.

NIGHTCAPS AND DREAMS.—Dr. J. Mortimer Granville, of London, has been urging the use of the nightcap as a preventive of dreams. Apropos, a correspondent of the New York Times urges the use of the corset as a preventive of "taking cold."

THE COST OF CREMATION at Gotha is about $50. The cost of the crematory was $25,000.

Dr. Roswell Park has resigned the editorship of the Weekly Medical Review to the former assistant editor, Dr. Robert Tilley.

THE MEETING OF THE NEW YORK STATE MEDICAL SOCIETY.—Members and delegates of this city and Brooklyn intending to go to Albany, can get round-trip tickets at reduced rates by sending their names to Dr. C. L. Dana, 66 West Forty-sixth Street, Secretary of the New York County Delegation.

We are informed that the New York Central and the West Shore railroads will probably give reduced rates to physicians coming from other parts of the State.

DEATH OF ROBERT B. TOLLES.—The most eminent maker of microscopic objectives in the world died in Boston, on December 17th, aged sixty-two years. His death seems to be an irreparable loss to science.

NATIONAL MEDICAL UNIVERSITY.—A bill has been introduced into the United States Senate to appropriate $1,000,000 as an endowment for a National Medical University at Washington, and $100,000 additional for ground and buildings. The bill proposes to recognize all forms of practice.

LEPROSY AND ELEPHANTIASIS are common and widespread throughout Mexico, and is most abundant in the States of Mexico and Sonora. It occurs mostly in the tubercular and anesthetic forms, though the macular is often found.
THE ARCHIVES OF MEDICINE is to be continued, as heretofore, under the direction of Dr. E. C. Seguin.

PROFESSOR HUXLEY is to receive a baronetcy.

THE NEW YORK INFANT ASYLUM.—At the last meeting of the Board of Managers the following officers were elected: Honorary President—Joel Foster; President—Clark Bell; First Vice-President—A. S. Hatch; Second Vice-President—W. H. Guion; Secretary—Richard B. Kimball; Treasurer—Levi M. Bates; Executive Committee—Levi M. Bates, Clark Bell, William N. Blake- man, Joel Foster, William H. Guion, Richard B. Kimball, Archibald Turner, Benjamin A. Willis, and A. S. Hatch. Of the other committees chosen Mr. Bates is Chairman of the Finance Committee, Dr. Foster of the Committee on Adoption, and Mr. Turner of the Auditing Committee. The Medical Board elected is as follows: W. R. Birdisall, A. N. Bell, F. H. Bosworth, Edward Bradley, C. L. Dana, George B. Fowler, William F. Wittendorf, William J. Morton, Henry G. Piffard, O. D. Pomeroy, F. M. Warner, H. Marion Sims, J. Lewis Smith, J. Clarke Thomas, William H. Welch, Charles F. Stillman, and J. S. McNamara.

THE CARTWRIGHT LECTURES OF THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS will be delivered by Professor Burt G. Wilder, M.D., of Cornell University, in the hall of the Young Men’s Christian Association, corner of Fourth Avenue and Twenty-third Street, on the evenings of Saturday, February 2d, Monday, February 4th, and Wednesday, February 6th. General subject: “Methods of Studying the Brain.”

February 2d, Limitation of the subject to macroscopic encephalic morphology; methods of regarding the brain based upon its condition in embryos and in amphibias. February 4th, Methods of preserving and examining the brain. February 6th, Methods of figuring and describing the brain.

THE COLLEGE OF MIDWIFERY AGAIN.—We have received a letter from Dr. John Aldorf, stating that he has resigned unconditionally from the College of Midwifery and has severed all connection with the institution. This he did as soon as he could after the publication of the “confidential cards” and pamphlet. Dr. Aldorf sends us also a full account of the history of the College, but his letter was received too late to be published in full. He states, what we do not doubt, that the institution was founded in good faith and to fulfil a useful purpose. He acknowledges himself to be the author of the pamphlet, “Woman’s Field of Work,” and defends its character. It was, he said, intended to reach a class other than medical men and to interest them in opening up the new field for women.

He continues: “The insertion of advertisements in the book has also been criticised. It being considered perfectly legitimate for most medical journals to reduce the expenses of publication in this manner, it is unnecessary to say anything further on this point. As to the recommendation of certain articles in the text, I believe there were five in number, an ‘Infant’s Food’ and ‘Malt Extract’ (endorsed by Professor Lusk in his work on ‘Midwifery’), a ‘Medicinal Wine’ (endorsed by Professor Bartholow, in his work on ‘The Practice of Medicine’), and a ‘Tar Soap’ and ‘Disinfectant,’ which have received the universal endorsement of the profession for the purposes for which they were recommended. The ‘circular’ and ‘confidential card’ met with my disapproval when first presented; but, being in the minority, my only remedy was to withdraw and sever all connection with the college, which I have done.”

We can only say now, in reference to one point, that because a gentleman recommends some article in a systematic treatise, no one has a right to append it to an advertising circular.

PROFESSOR REICHERT, late Professor of Anatomy in the University of Berlin, died recently at the age of seventy-three. He has been succeeded by Waldeyer, of Strasburg.

M. DADASCHINO has been made Professor of Internal Medicine in the Faculty of Medicine of Paris.

WOMEN PHYSICIANS IN THE PARIS HOSPITALS.—At the recent competitive examinations for the post of externe to the Paris hospitals, three women physicians passed successfully. There were 254 candidates. Madame Sarrante passed sixth, and Madame Chopin one hundred and forty-second.

THE NEW UNIVERSITY AT PRAGUE.—The medical department of the new University at Prague has been organized and the professors appointed. Among these Spina, of Vienna, and Tompa, of Kiel, are best known.

AUTOBIOGRAPHICAL NOTES BY THE LATE DR. J. MARION SIMS.—In Harper’s Monthly for February is an interesting story by the late Dr. J. Marion Sims, entitled “Lydia Mackey and Colonel Tarleton.” It is a revolutionary sketch, and is taken from autobiographical notes left by Dr. Sims, who was a great-grandson of Mrs. Mackey.

A DENTAL INSTITUTE is to be added to the Berlin University, and plans for its organization have been submitted to the medical faculty.

A NEW DECISION UPON THE MEDICAL LAW OF NEW YORK.—The County Medical Society recently brought suit in the Court of Special Sessions against a Dr. Desiré A. Protin, for practising medicine without first having had his diploma countersigned by a medical college in this State. The defendant made the plea that the possession of the diploma was sufficient, but this was denied by the Court and decision rendered against him. Appeal, however, was made and the decision reversed in the Court of General Sessions. Accordingly, as matters stand now, the provision of our medical law, which obliges medical graduates from other States to have their diplomas countersigned, is void.

LEGISLATION FOR THE EXTINCTION OF PLEURO-PNEUMONIA.—The Chairman of the House Committee on Agriculture, on January 15th, submitted a memorial signed by a number of dealers in live stock, asking for legislation to protect their interests. The memorialists refer to the losses which the live stock interests of the country suffer by reason of the restrictive regulations now enforced by foreign governments against the importation of American live stock and meat products. They ask Congress to provide means for the extinction of pleuro-pneumonia, and this they say can only be done by the slaughter of all infected cattle. The memorial further
says that the members of the United States Cattle Commission, who have made a very thorough examination of this subject, estimate the expense of such a measure at $1,500,000. In the opinion of the memorialists not more than $500,000 need be made immediately available. The memorial further recommends, with a view to removing the prejudice of foreign customers, that a rigid system of inspection of all meat products for export be provided for and enforced, the expense of such inspection to be borne by the exporter.

The Kansas City Medical Record is the title of a new monthly journal published in Kansas City. It has a better appearance than most Western monthlies.

New Journals.—The Archives of Pediatrics is the title of a new monthly journal devoted to diseases of children, edited by Dr. Watson, and published in Jersey City. Its first issue is well made up and contains a number of valuable papers.

New Haven Medical Association.—The annual meeting of this society was held Monday evening, January 7, 1884. The report of the Secretary showed that during the past year twenty meetings had been held, at which the average attendance was sixteen. The membership is smaller by three than a year ago. Two members have removed from the city and one has been expelled, leaving fifty-one active members in the association. The following officers were elected: President—Dr. Frank E. Beckwith (second term); First Vice-President—Dr. W. R. Bartlett; Second Vice-President—Dr. M. A. Cremin; Secretary and Treasurer—Dr. H. Fleischner; Prudential Committee—Drs. M. C. O'Connor and W. O. Ayres; Financial Committee—Drs. Francis Bacon and T. P. Gibbon.

The Medical School of Maine.—Efforts are making to secure the removal of the Medical School of Maine from Brunswick to Portland.

Death of Dr. Henry A. Du Bois.—Dr. Henry Augustus Du Bois, a native of, and for many years a resident of this city, died January 13th, at his residence in New Haven, Conn., where he has made his home since 1854. Dr. Du Bois was born in this city, August 9, 1808. He graduated from Columbia College in 1827, and from the College of Physicians and Surgeons in 1830. He then went to Europe, where he studied for three years. In 1834 he began practice in New York City, and speedily attained much prominence, largely because of his enthusiastic defence of many novel practices and opinions which he had gathered from his European experience. Dr. Du Bois became especially prominent during the scarlet fever epidemic of 1838. He then took a stand in the treatment of this disease directly contrary to the laws set down in the books and the theories in practice. He considered the epidemic as asthenic in character and unsuited to the severe antiphlogistic treatment which then prevailed. He held the disease to be determinate, and that it must run its regular course. He disbelieved the idea that the disease could be "jugulated" by active treatment. He is said to have been very successful in his treatment—quinine and a supporting regimen—while those who held to the antiphlogistic system were less successful in their practice. In 1840 Dr. Du Bois abandoned the practice of medicine. Since then he has been engaged in mercantile, scientific, and literary pursuits. He was a member of the New York Lyceum of Natural History, and of the New Haven County Medical Society. He received the degree of L.L.D. from Yale College in 1864.

Medical Legislation at Washington.—A number of bills relating to medical matters have been introduced into the Senate or House of Representatives. A bill has been introduced into the Senate which aims to create a Bureau of Animal Industry, which Bureau shall supervise matters of cattle quarantine, veterinary police, and sanitation.

A bill appropriating $200,000 for the erection of a fire-proof building for the use of the Army Medical Museum and Library has been introduced into both houses. There is a House bill providing for the removal of the tax on alcoholic liquors that are to be used for medicinal purposes.

The President has sent a message recommending the representation of the United States in an international convention for the establishment of definite and uniform standards of examination for color-blindness and tests of visual acuteness.

The Quadrennial Prize of the Worshipful Company of London Grocers.—The above company has recently distributed circulars particularizing the conditions on which the prize of £1,000 is offered. The circular announces as the subject of competition the following: "To discover a method by which the vaccine contagium may be cultivated apart from the animal body, in some medium or media not otherwise zymotic: the method to be such that the contagium may, by means of it be multiplied to an indefinite extent in successive generations, and that the product after any number of such generations shall (so far as can within the time be tested) prove itself of identical potency with standard vaccine lymph." The prize is open to universal competition, British and Foreign.

Competitors for the prize must submit their respective treatises on or before December 31, 1886; and the award will be made as soon afterward as the circumstances of the competition shall permit, not later than the month of May, 1887.

It may prove that the problem is already solved by a physician of Finland, Dr. Quist, who has studied the subject very thoroughly from many points of view.

Honors to Medical Men.—The title of Hofrath has been conferred upon Dr. Stillwag v. Carion and Professor Spath, of Vienna. Professor Carl von Voit, of Munich, has been granted the Maximilian Order of Science and Art.

At a Memorial Meeting held in Honor of the Late Dr. J. Marion Sims, at Charleston, S. C., the following interesting address was delivered by Dr. R. A. Kinloch:

Mr. President: Although I can add but little to what has already been said by my friends, who have so well and so fully spoken, I cannot refrain from offering my mite as a tribute to the memory of the genial, warm-hearted, charitable, talented, and great man whose death our profession now mourns.

To those who ever met Dr. Sims his personal magnetism appeared as his characteristic feature. This was the offspring of his softness of manner, his kind words for
others, his exhibition of that professional enthusiasm and elasticity of spirits that prevented him from knowing any such thing as failure in the work he had at heart. One felt at once a love for him at the first meeting. No man had fewer enemies. And although in the buffetting, which comes necessarily with professional emulation, there were encountered some bitter feelings and some unfortunate jealousies, these did not long mar the evenness of his life. He died, I believe, in charity and at peace with all men. He felt for others more than they felt for him, and more perhaps, at times, than he felt for himself. Upon the most trying occasion of his life, when he thought proper to resign his position at the Woman's Hospital, whether he was altogether right or altogether wrong, it is certain that the heart of our great profession extended to him a spontaneous and unlimited sympathy.

Of his kindness of heart and his thoughtfulness of others I may relate a striking incident associated with myself. Three winters ago, when he was in this city, and upon a bed of sickness, which at one time it was feared would be his bed of death, I sat by his side upon one of the occasions of my daily visits to him. He had been talking a little, though he was very weak, and it had pleased him to refer to some trifling attention on my part which had merited my "goodness." Suddenly, however, he grasped my hand and said: "My dear doctor, I am going to find fault with you in regard to one matter." I asked him what it was, and told him I would listen. He said, "Why did you write that review of my friend —'s book?" alluding to an old review of my own in The Medical Journal, which I formed the best and, I thought, proper, and asked if he regarded the criticism as unjust. "No," he replied, "not that, but he (the author) is a good fellow, has done some good things, and you ought not to have been so hard on him." I accepted the argument without admitting its legitimacy, and did not reply. The asperities of my own nature were softened as I looked upon the good, ill, near, and far, yet thoughtful of the tender feelings of a distant professional brother.

But to speak of the professional ability, the high qualifications, and the striking success of our friend, and to trace these to their source, is also a useful professional lesson to us. There was no great intellectuality that interested success. The deplorable fact of the first line badly written of ordinary capacity elicited simply the love of his fellow-students. The enthusiasm of his nature, however, when he came to manhood, was duly recognized, and in the young physician and surgeon there began to appear mechanical ingenuity and persevering effort, together with originality and boldness. Fortunately, for him he was long a "general practitioner," and he had enjoyed a field for investigation and practice with the negro race with which our Southern young men were often favored anterior to our civil war. His surgery in female diseases was thus first cultivated with the crudest specimens of the sex, it culminated with the refined women of the boasted aristocracy of Europe. Thirty or forty operations on one female were the first task of the student, and after one failure with the other to insure loss of reputation! What a commentary upon professional experience!

When Dr. Sims finally made the effort to make gynecology a special department of practice, he succeeded mainly because of his training as a physician, or more especially as a surgeon. He presented, then, a striking contrast to many who in our day have narrowed down this work and who succeed only poorly and by reason of the credulity of trusting woman.

Dr. Sims had the lady's hand and the lion's heart, a tender sympathetic nature and an enthusiastic spirit which could not fail to carry him on to victory.

So one better than he appreciated the delicate nature of a refined woman; no one realized more than he that woman's gratitude surely followed the healing of her infirmities. We may try, to estimate his loss by reviewing his qualities of head and heart. We may raise to him a monument, as elsewhere proposed, in that beautiful park of his adopted city, near the fields of his triumphs and the homes of the many who loved him well, but at last, for the true valuation of his greatness, we must look to those of the gentle sex who felt the marvellous nature of his professional work. More precious than the brass and the stone of the loftiest column is the inscription that commemorates the virtues of the dead. No monument to the Father of American Gynecology will be complete unless the inscriptions come from the grateful heart of a refined and appreciative woman.

THE SIMS MEMORIAL FUND.

To the Medical Profession and Others throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting testimonial than obituaries and eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations, and such as have had the direct advantage of his "lady's friend," will join me in the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulse to the study of gynecological surgery in America. It is believed that the medical profession everywhere, the vast number of women who owe their relief from suffering directly to him, and those who realize the beauty of his art and will gladly unite thus to honor the man through whose original and inventive genius such blessings have been conferred upon humanity.

At the suggestion of many friends, therefore, the subjoined committee has been organized, and it is proposed that a suitable monument be erected to his memory in the city of New York.

To this end the active co-operation of the medical profession and the many other friends of Dr. Sims throughout the world is respectfully solicited. Contributions of one dollar and upward may be forwarded to the journal which has been constituted the treasury of this fund—The Medical Record, New York.

FORDYCE BARKER, M.D., Chairman.

GEORGE F. SHRADY, M.D., Secretary.

THOMAS ADDIS EMMET, M.D., New York.

T. GAILLARD THOMAS, M.D.,

WILLIAM T. LUSK, M.D.,

WILLIAM M. POLK, M.D.,

PAUL F. MUNDE, M.D.,

NEW YORK PATHOLOGICAL SOCIETY.

Anniversary Meeting, January 9, 1884.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

TUBERCULOSIS OF THE TESTICLE.

DR. A. G. GERSTER presented three testicles, not so much on account of the rarity of the disease for which they were removed, as the fact that they illustrated the gradual development of tuberculous of the testicle.

The first showed the most recent stage of the disease, and was removed from a laborer, thirty-eight years of age, who noticed an increase in the size of the left side of the scrotum, and first presented himself at the German Dispensary, where the diagnosis of hydrocele was made. The epididymis being rather swollen and hard, and the swelling extending up the spermatic cord for some distance, it was a question whether the hydrocele was simple or symptomatic of disease of the testicle. There was no evidence of pulmonary disease. The patient could assign any cause for his difficulty. He said he had never had gonorrhea, and there was no evidence of urethral stricture. Dr. Gerster proposed first to operate for the hydrocele, and accordingly performed Vollmann's radical operation about seven weeks ago, thinking that possibly the swelling of the testicle and epididymis would so diminish as to render further interference unnecessary. The wound healed kindly, the walls of the sac adhered to the testicle, and the patient was discharged from the hospital at the end of two weeks. Five weeks afterward he reported having had a severe chill and a very bad night. One week later the patient had lost his appetite and had commenced also to lose flesh. Dr. Gerster advised immediate removal of the testicle. The puncture was made, and the fluid was removed. The testicle showed a large central hard mass, denominated crude tubercle by the old writers. The epididymis was hard and enlarged. There was no evidence that the process of breaking-down had begun at any point. When the specimen was fresh the central nodule had a pale yellowish, waxy appearance.

The second was not so large, but from a patient, thirty-one years of age, who had suffered from severe compression of the testicle. Acute traumatic epididymitis and orchitis followed, which did not run a normal course, but terminated at the end of six or eight weeks after the injury in a painless, hard, and smooth swelling of the organ, and the enlargement and induration extended up to the external abdominal ring. The patient had chills and night-sweats, and had emaciated considerably. Dr. Gerster removed the testicle, and it was interesting mainly on account of the condition of the tunica vaginalis, which presented an appearance resembling very much that seen upon the synovial membrane of diseased joints—namely, the velvety appearance with masses of newly formed granulation tissue at several places. In this specimen there were two central nodules of tubercle, and each had gone on to softening, so that small cheesy masses could be readily squeezed out.

The third specimen had a large central focus, consisting almost wholly of broken-down tissue with a sufficient reteculum to hold the semi-fluid mass together. It was removed from a patient, twenty-four years of age, and originated in an ordinary gonorrhoeal orchitis, in which swelling and pain remained stationary. The epididymis also was involved. Eight or nine weeks after the first attack the patient began to suffer from chills and sweats, had lost flesh, and suffered a great deal of spontaneous pain. Dr. Gerster at once removed the organ. In this instance the tunica vaginalis had been spontaneously obliterated.

Pathologically these specimens were interesting be-

cause they illustrated the disease in three stages. They were interesting surgically because they demonstrated that an early diagnosis of the disease can be made. In former times it was the practice to allow such cases to go on until hernia testis developed. Dr. Gerster, however, believed that no special meaning could be correctly attached to the condition of hernia testis, because it is a symptom of several disorders occurring in the testicle.

Dr. VAN GRESHON asked if, at the time the emaciation occurred, preceded by chills and night-sweats, an examination was made and no evidence of tuberculous disease detected in any part of the body.

Dr. GERSTER said that an examination was made, that there were no symptoms of tuberculous disease, and that none had developed since the operations, the patients being still under his observation. There was no family history of phthisis in either case. In the case in which the disease was most advanced, the patient a few days before the operation said he had a hacking cough and demanded that the organ be removed. He had already diagnosed tubercular orchitis unaccompanied by tuberculous of any other organ, and the nature of the affection and its liabilities had been explained to the patient. Dr. Gerster thought solitary tubercular disease was not uncommon, and could very easily go out, especially when seen early, as in these cases, and when it is unilateral. He believed the so-called "conservative treatment," consisting of scraping out the fungosities, replacing the protruding masses, etc., were all pernicious, and that the only rational treatment was immediate removal of such a focus from the body, as it may be a centre for the development of general disease.

Dr. WENDT asked if the general symptoms disappeared soon after removal of the testicle.

Dr. GERSTER said they disappeared at once.

Dr. WENDT thought it a fair inference, therefore, that the local disease was the cause of the general symptoms.

The PRESIDENT said it was an established fact in surgery that with the removal of such local lesions there was a subsidence of the general symptoms.

Dr. FERGUSON asked if military tubercles had been found about the border of these masses, and also if the character of the white pulp mass in the last specimen had been ascertained microscopically.

Dr. GERSTER said not, but his specimens had been examined microscopically and he would be pleased to have them referred to the Committee on Microscopy. They were so referred.

GENERAL TUBERCULOSIS—PARENCHYMATOUS NEPHRITIS.

DR. FRANK FERGUSON presented a series of specimens for which, together with the clinical history, he was indebted to Dr. Beverley Robinson, Attending Physician at St. Luke's Hospital.

A male, thirty-five years of age, a native of England, and a paper-hanger by occupation, was admitted into St. Luke's Hospital on December 19, 1883. His father died of carcinoma of the stomach. He denied syphilis; neither had he had any previous fever. He had had yellow fever, and was a moderate drinker.

Six months previous to his admission he was seized with general pains all over his body; dyspnoea on exertion, at the same time there was hemorrhage from some part of the respiratory tract, and his appetite became poor. His dyspnoea on exertion and poor appetite continued; he had a cough but not continuously. One month ago he had a chill; developed a continued cough with muco-purulent expectoration, but was able to do some work up to the time of his application for admission. On examination there was dulness over the upper lobe of left lung, posteriorly also over the lower lobe of the right lung. Harsh and bronchial breathing, prolonged expiration, and rales were heard, generally distributed over the chest anteriorly and posteriorly. These signs were
more marked over the upper than over the lower lobes of the lungs. His heart action was very weak, and rapid. His temperature ranged from 99° to 103.5° F., higher in the afternoon, and his respiration was rapid, labored, and shallow. He was put on appropriate diet and stimulants were freely administered.

His urine, submitted to the ordinary tests and methods of examination, was found negative.

Five days after admission he became delirious, and the delirium continued with interruptions until his death on December 27, 1883.

The autopsy revealed adhesions old and recent over the right side, and the portion of lung covered by recently exuded lymph was the surface of the middle lobe. The upper portion of the upper lobe had an interlobar axillary line. The old adhesions were generally distributed over the surface of the lower and upper lobe. The lungs were everywhere pervaded by miliary tubercles, and in the upper lobes of both organs were numerous very small cheesy masses. The bronchial tubes were congested and contained mucus and pus; there were no cavities. The heart was normal in size, the valves were competent, the muscular tissue was anemic. The spleen was large, soft, and pigmented. Neither with the naked eye nor with the aid of the microscope could any tubercles be found. The kidneys were normal in size; capsules were not adherent, their surfaces were smooth and congested; and there were a very large number of small tubercles in the cortex. Under the microscope fresh sections of these organs showed cloudy condition of the epithelium of the tubules of the cortex, and in places fatty degeneration. A few casts, hyaline and granular, were also observed in the straight tubules of one of the pyramids. The ureters and bladder were normal. The liver was large, contained a good deal of fat, and was covered with numerous young miliary tubercles. The tubercles in the liver do not, as a rule, show cheesy centres; only accumulations of young cells with one or more giant cells. In the kidney many of them were typical tubercles with cheesy centres. Tubercular bacilli were seen in great numbers in the tubercles of the lung; the other organs had not been examined for them.

The case was interesting, first, because an accurate diagnosis had been made, and the post-mortem showed that the different râles noted in the clinical history of the case can occur intra-pulmonary. Second, tuberculosis so general in both lungs without any cavities. Third, the tubercles in the kidneys, but especially in the liver, are very young and afford an opportunity to study them at an early date. Fourth, the lesion of parenchymatous nephritis is possible in tuberculous kidneys. Unfortunately an examination of the head could not be obtained.

Dr. Wendt asked if there was any suspicion of the existence of tubercles in the kidneys during life. The reason he asked the question was because recent German writers had claimed that tubercle bacilli can be found in the urine.

Dr. Ferguson said there was no suspicion of this character further than that the attending physician entertained the conviction that it was a case of acute general tuberculosis. The urinary examination, not made for bacilli, however, was negative.

Dr. Heineman presented Specimens Illustrating Empyema—Acute Pericarditis—Acute Pulmonary Tuberculosis, in a child eighteen months of age, which was admitted to the Mount Sinai Hospital, November 31, 1883. The child had measles nor scarlatina. It had whooping-cough nine months previous. Three months previous to admission it was ill with diaphtheria for three weeks, and immediately afterward had pneumonia, from which it never fully recovered. It had more or less constant fever, cough, and severe dyspnoea. Appetite had remained good. Slept poorly only at times.

On admission the child was markedly emaciated and pale, had severe dyspnoea, rapid pulse, 180 and feeble; respiration, 80; temperature, 103.5° F. Physical examination gave flatness and absence of respiratory murmur over the whole of the left chest. Heart displaced downward and to right of epigastrium. The aspirator detected pus in left chest.

Nowever, there was an incision made in eighth interspace in first axillary line, five ounces of pus escaped, and a drainage-tube was inserted. Subsequently a counter opening was made anteriorly. The temperature fell to normal, the respirations to 60 and 64, the pulse became better, the child improved, and the discharge of pus grew smaller, though it was still decided at death. On November 26th the temperature rose temporarily to 102.9° F., and respiration to 80; were normal next day. The patient was otherwise comfortable, appetite was moderate. The child continued to emaciate, however, and with a normal temperature, pulse varying between 120 and 160, respirations being a little over 60, only rising occasionally to 80, died quietly without other symptoms, December 14, 1883.

The autopsy revealed the following condition: Brain not examined. Lungs: Right lung—Upper lobe completely consolidated and in stage of red hepatization and contained recent small cheesy nodules; lower lobe cedematous. Scattered through lung were also grayish translucent miliary nodules. Left lung firmly compressed by a large pleural effusion, but the borders were intact, covered with a rather thick layer of fibrin and pus. Left pleural cavity lined throughout with considerable layer of fibrin and pus and contained about an ounce of healthy pus. Two artificial openings existed into the cavity which appeared healthy; ribs were unaffected. Heart: Pericardial sac enormously distended with purulent serum, several centimeters. Pericardium rather thick, covered by a thick layer of fibrin and pus. The other viscera were normal.

Dr. Ginney asked Dr. Heineman if the diagnosis of pericarditis was made before death.

Dr. Heineman answered that it was not.

Dr. Ginney thought it was not easy to diagnose pericarditis in a patient suffering from empyema. He cited a case in which he made an autopsy last spring, one that had been under observation for some time, and in which several prominent medical men had been interested. The child had marked empyema, which was opened by incision, and the patient died from exhaustion following a very small hemorrhage. On opening the chest the pericardial sac was found completely filled with pus, therefore not the mouse-like condition during life.

Dr. Heineman also presented specimens of Tubercular Ulceration of the Prostate with Tubercular Kidney, and Hydrenephrosis.

Jacob R., aged twenty-nine, native of Germany, married, and a tailor, was admitted to Mount Sinai Hospital, December 23, 1883. Family history negative. Never had gonorrhoea nor chancre. Never had rheumatism. Was perfectly well until four years ago, since then he had at times pain across the bladder, frequent and painful micturition, incontinence at times, retention at others, and frequently suffered from vesical tenesmus. Quantity of urine scanty, always cloudy in appearance, but never bloody. He had had backache, but no other symptoms of renal disease. His appetite has been poor, and the bowels constipated.

For four years, previous to six years ago, he had the habit of masturbating; for two years past was married; was moderate in intercourse, and had seminal emissions sometimes. He had had a peculiar chilly feelings almost daily for the past nine months.

Upon admission he was found to be markedly anemic, emaciated, and appeared utterly without animation. His bowels were constipated, and his appetite poor; had no cough, and complained of his urinary trouble as above described.
Physical examination of the lungs revealed râles over both sides, and here and there slight dulness, and respiration slightly rube. His pulse varied during his stay in the hospital from 58 to 60; his respirations from 22 to 36; his temperature 97° to 99.2° F. His urine varied in specific gravity from 1.004 to 1.014, was frequently acid, sometimes alkaline, and contained considerable pus and albumen; the quantity varied, being respectively seventeen, twenty-four, twenty-two, ten, and six ounces per day.

He complained but little, had a constant odor of urea of the breath, seemed always in a condition bordering on coma, and on fifth day of admission became comatose, and died December 29, 1883, the sixth day after admission.

At the autopsy both lungs contained small recent cheesy nodules and were thickly studded with translucent grayish miliary nodules. The heart was normal. The liver was cirrhotic and about normal size. The spleen was increased in size and saxy. The stomach and intestines showed the lesions of chronic catarrhal inflammation. The right kidney was the seat of hydropneumothorax, somewhat smaller than normal, the proper kidney tissue was converted into a mass of sacs with thick connective-tissue walls. The pelvis and these sacs were distended and filled with a thick pasty mass of impregnated pus and cheesy matter. The ureter was slightly thickened. The left kidney was enormously increased in size, measuring eight inches long and four and a half sides. On section it was found to be uniformly hypertrophied throughout. The mucous membrane of the pelvis was reddened and, on section, a fatty contained pus and cheesy material. The kidney itself contained several large cheesy cavities and was studded with small and large foci of pus. The left ureter was markedly dilated throughout, and its walls hypertrophied, its size corresponding with that of the hypertrophied kidney. The pelvis of the left kidney is the seat of tuberculous ulceration and was broken down. The coats of the bladder were thickened and the mucous membrane coated with thick layers of fibrous pus and cheesy matter. Microscopic examination revealed presence of bacilli in the ulcerating mucous membrane.

DR. FERGUSON asked if the kidneys had been examined microscopically, and if they showed evidence of chronic diffuse nephritis.

DR. HEINEMAN said they had been, and that the lesion mentioned was present.

DR. FERGUSON remarked that the reason why he asked the question was because one of the members, at a recent meeting, stated he had examined three hundred tuberculous kidneys, and that in not one of them was chronic diffuse nephritis present.

HYERTROPHY OF THE HEART—DIAPHRONOUS INTERVENTRICAL SEPTUM.

DR. ROBINSON presented a heart removed from the body of a man who was admitted December 20, 1883, to St. Luke's Hospital, suffering from pulmonary tuberculosis. Nothing abnormal concerning the heart was discovered before death.

At the autopsy the heart was found enlarged, fatty, but the valves were competent. The muscular tissue had undergone fatty degeneration. The inter-ventricular septum at its upper portion was composed of fibrous tissue and was diaphanous. There were cavities in the lungs, and also miliary tubercles. There were tubercles in the kidneys. There was one ulcer in the jejunum. The liver was fatty and anemic.

URETHRAL STRICTRUE—CYSTITIS—PYELITIS—PNEUMONIA—ENDOCARDITIS.

DR. Beverley Robinson also presented specimens accompanied by notes of the history furnished by Dr. W. H. Sherman, Acting Senior Assistant Physician at St. Luke's Hospital. John F. R., twenty-four years of age, a druggist by occupation, was admitted December 26, 1883. No family history of hereditary disease. In 1879 the patient had an attack of acute parenchymatous nephritis, he stated when urine albumen, but no casts. Since then he had occasionally found albumen in his urine. Present illness began on December 13th. He was attacked with dizziness and vomiting. Had vomiting and daily chills up to the time of admission. Had no fever on the day of admission or before (patient had been accustomed to take his own temperature). Bowels were regular, there was no admission in his urine but no casts. Since then he had occasionally found albumen in his urine. Present illness began on December 13th. He was attacked with dizziness and vomiting. Had vomiting and daily chills up to the time of admission. Had no fever on the day of admission or before (patient had been accustomed to take his own temperature). Bowels were regular, there was no admission in his urine but no casts. Since then he had occasionally found albumen in his urine. Present illness began on December 13th.

He had deep-seated tenderness over the region of the left kidney behind, and, on deep pressure, over the left side of the abdomen. He had no muscular contractures. His tongue was dry and coated, and there were sordes on the teeth. His pulse was 102 and feeble. His temperature was 98.3° F. in the mouth. The patient had a stricture of the urethra, situated about two inches from the meatus, the result of a gonorrhœa acquired seven years before. His heart was somewhat enlarged and there was a rough murmur covering the first normal sound, heard at the base at the inner end of the second intercostal space, over the mid-considerable area between the nipple and the sternum, and conveyed into the great vessels.

December 27th.—Urine was drawn with a catheter, and ten fluidounces obtained during the twenty-four hours. Patient had a slight sweat. Given sulphate of quina (gr. v. every eight hours) and murirota potassium nitritus (gr. 3. every three hours). Temperature, morning, 98.2°; evening, 97.2°.

December 28th.—The urine had a specific gravity of 1.010, an acid reaction, ten per cent. of albumen, some pus, and a few red blood-globules. The vomiting continued. The pulse became very weak, irregular, and diaphoretic. A catheter containing acrid semen was introduced. The patient was somewhat delirious during the early part of the evening. The pupils became moderately contracted, the respiration slow and labored; the temperature fell in the axilla to 94°, and he died December 28th at 9:05 P.M. There were neither convulsions, muscular twitchings, uriniferous odor, nor oedema.

The autopsy was performed by—Rigor mortis well marked; no oedema. Lungs: Right—upper and lower lobes were intensely cedematous and congested; the middle lobe was hepatized, being in a condition midway between gray and red hepatization; bronchial tubes contained frothy mucus and some pus; there were old adhesions on the left side posteriorly. The left lung was congested and edematous. The heart was normal (attending physician found beading on aortic valves). Spleen normal. Kidneys small; capsules not adherent; surfaces very granular; cortices thin; markings indistinct. Left kidney is anemic; right kidney is markedly congested; pelvis of both are intensely congested and covered with pus. No evidence of amyloid degeneration. Liver small and deeply pigmented. Intestines: The solitary follicles and Peyer's patches of the small intestines are prominent. Bladder: Far advanced cystitis; contains some urine and pus. Urethra: A stricture existed about three inches from the meatus, which admitted sound No. 8, English.

The case just read is of interest for several reasons:

First.—Although after death a well-marked consolidation of the middle lobe of the right lung was found, during life there was neither cough nor spuia, nor did the stethoscopic signs reveal to him, by aught else save deficient respiratory murmurs, the possible condition of the right lung.

Second.—The patient had during life a rough murmur synchronous with the first sound of the heart, and heard over an area where we are accustomed to locate murmurs pointing to aortic stenosis. Although prior to death he was confident that the autopsy would show ad-
vanced aortic lesion, in fact there is only a slight beading of the aortic cusps to show as the organic cause of the murmur heard during life.

Third.—Although it would appear from the man's history that the stricture of the urethra was an efficient cause, doubtless, in producing his affection of the kidneys, yet the kidneys themselves are not such as are usually seen following upon this condition. Instead of being enlarged with a much distended pelvis and the cortex and pyramidal portion infiltrated with cheesy nodules, they are small and contracted and present the condition of well-marked interstitial nephritis. The question which presents itself is whether the kidney degeneration is not really independent of the stricture of the urethra, except perhaps the late inflammatory condition of the pelvis. In favor of this belief we note the hypertrophy of the left ventricle and the secondary pneumonia. Opposed to it we have the somewhat chronic inflammatory condition of the bladder, which is so frequent a sequela of old and neglected stricture of the urethra.

Dr. Robinson asked if the condition of the kidneys was common without urethral difficulty.

Dr. Peabody remarked that such kidneys are far more common without than with urethral trouble.

PERNICIOUS INTERMITTENT FEVER—PIGMENTED BRAIN, LIVER, AND SPLEEN.

Dr. G. L. Peabody presented the liver, spleen, and brain removed from the body of a man who died of pernicous intermittent fever. The patient was thirty-one years of age, a German, who had been in Jamaica. How long he had been suffering from the symptoms presented Dr. Peabody was unable to say. He complained of severe headache, was in a condition of lassitude, but was able to give short answers to questions, and within twenty-four hours passed into coma and died with a temperature of 108° F. There were no renal complications. Dr. Peabody had examined sections of the brain and liver microscopically and found blood pigment present in both in large quantity. In the brain it was where he had always found it, chiefly in the gray matter and entirely confined within the lumen of the blood-vessels. The Society then went into executive session.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 17, 1884.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

DR. R. F. WEIR GAVE

A DEMONSTRATION OF ANTISEPTIC DRESSINGS AS THEY ARE USED AT THE NEW YORK HOSPITAL.

The principles embodied in the dressings remain the same as when set forth by Sir Joseph Lister, and in the treatment of wounds the aim is to place the parts in such a position as to secure the best drainage and keep them at rest (avoiding frequent renewals of the dressing). To accomplish this, substances which will prevent decomposition must be used, for this is either caused by micro-organisms or inevitably associated with the process. Whatever theories may be broached concerning the entrance of germs into the body, it is the aim of antiseptic surgery to neutralize conditions which favor the development of germs. Until recently this has been done by the use of carbolic acid and iodine.

A grave objection to carbolized gauze or jute, etc., is the fact that, however prepared, the carbolic acid evaporates and leaves the material, if not very fresh, an unreliable antiseptic dressing. One of the great objections brought against carbolic acid and also iodine is the fact that both are liable to produce toxic effects. We know a little more exactly concerning iodine than carbolic acid in this respect, and Neuber, of Keil, has demonstrated quite satisfactorily that of this drug forty-five grains can be used safely about a wound. About two years ago Dr. Weir began to use the bichloride of mercury, which has displaced, to a very considerable extent at least, both of the above antiseptic drugs. It is kept in contact with wounds by means of gauze covered with a solution, or by means of peat, first used at Kiel, and also jute, which fell into disuse because carbolic acid evaporated from it so rapidly. The bichloride solution used varies in strength from 1 to 1,000 parts of water to 1 to 5,000. One great advantage which it has over carbolic acid is durability, and a week ago Dr. Weir spoke of a solution that it was a very stable. But investigation proved that it is a rather unstable compound, that calomel forms at the expense of the bichloride, both in the solution and in the dressings (gauze, jute, etc.). To counteract this Professor Gibbs, of Harvard, had suggested the addition to the solution of a small quantity of common salt, say 5 parts to the 1,000.

To prepare the dressing, get the sizing out of gauze or cheese-cloth by immersing it in a weak solution of soda, or muriatic acid, or both, then washing it with water and drying it. Then immerse it in the following solution:

B. Bichloride of mercury .20 parts.
Water .4,480
Glycerine .500

which is a one-fourth per cent. solution, and allow it to dry. Cotton batting is prepared in a similar way. Jute and moss are prepared by putting them into a solution of bichloride, 1 part to 1,000 of water and 50 parts of glycerine, and allowing them to remain all night; when the water is wrung out and allowed to dry (the glycerine prevents them from doing so entirely). Dr. Weir then spoke of wood pulp, peat, bleached and pressed jute, moss, cotton, etc., and exhibited specimens of each, prepared for surgical dressings. These materials can be bought of M. Lienau, 2 Jones Lane, New York.

At the time of the operation a solution of bichloride, 1 to 1,000, sometimes 1 to 2,000 of water, is allowed to trickle nearly continuously over the incision, the parts having previously been thoroughly washed with soap and water and afterward with a solution of turpentine in alcohol, of the strength of two drachms to the pint. The parts should be washed the day before, as well as on the morning of the operation. The rubber bandage is applied (in amputation cases) and he uses the spray only in abdominal, thoracic, and joint operations. Hemorrhage is arrested temporarily by means of haemostatic forceps, of which Dr. Weir exhibited a large number, together with knives, having baked-rubber handles.

The vessels are ligated with catgut, prepared by placing the material in bichloride solution, 1 part to 100 of water, for ten minutes, and then a watery solution, 1 to 1,000, for ten to fifteen hours, and afterward wound on bobbins and kept in absolute alcohol. Occasionally Kocher's ligatures are used, prepared by placing catgut in oil of juniper for twenty-four hours, and then into absolute alcohol. Dr. Weir prefers, however, to use the ligatures of catgut, which he has kept in the absolute alcohol, with which he has kept them in the alcohol. The wound is closed with the continuous suture of catgut, leaving an opening at each end for the drainage-tube, that of black rubber being preferred. Dr. Weir spoke also of decalcified bone drainage-tubes, one disadvantage of which was that they were absorbed too quickly. This, however, can be subdued by keeping them in absolute alcohol. Cleanse the wound by injecting the drainage-tube until the solution comes out clear, then place a piece of sublimate gauze over the centre of the wound, over that other pieces, and over the whole a compress of several thicknesses secured in position by means of a bandage. The expectation is to have an amputation wound heal under one or two dressings.

The possibility of toxic absorption of the bichloride
solution has led some to use a milder antiseptic during the operations, such as that suggested by Thiersch, of Leipzig, and composed of

This is allowed to flow over the wound during the operation, the final washing being made with the bichloride solution. Cleanliness on the part of the operator and the assistants, as well as the patient, and everything about him, is presupposed, and the author of the paper referred especially to the operating-rooms of Tait and Keith, and the scrupulous care exercised by these gentlemen concerning cleanliness. Special reference was made to the way in which sponges can be made aseptic, and the care which they should receive after each operation. The sponges in the New York Hospital are prepared by first beating out the sand, then washing them in warm (not hot) water, and placing them in a solution of permanganate of potash, 1 to 1,000, of water, for twenty-four hours. Then wash out the permanganate with warm water, and bleach by immersing them in a solution composed of one part of sulphite of soda to one hundred parts of water, to which has been added a one-fifth part of a watery solution of chloroform at the strength of 8 parts to 100. Only a few minutes are required to whiten them, and if left longer they become brittle. The sponges are then put into a carbolic solution of 1 to 20, or in a bichloride solution of 1 to 1,000, where they remain until used. Sponges prepared in this way cost about a cent and a half each, and can therefore, without much expense, be used over and over again after each operation. For simple lacerated wounds Dr. Weir preferred iodiform.

Finally, absolute rest, so far as possible, is enjoined, and this is secured (in cases of amputation, etc.) by means of the tin splint enamelled.

To use a common expression, Does all this detail pay? He regarded it like discussing a self-evident proposition, but to show the value of antiseptic treatment a few figures were presented. Prior to the use of antiseptics the mortality from compound fractures of the thigh and leg, arm and forearm, was over thirty-three per cent. in Roosevelt and St. Luke's Hospitals; in the old New York, sixty per cent.; in the Boston City Hospital, forty-one per cent.

Under the open treatment the mortality was reduced to twenty-six per cent. Under antiseptic treatment he had had one hundred and eighteen major compound fractures, with eight deaths, a mortality of six per cent. Lately he had had twelve cases of compound fracture treated with the bichloride dressings, without a single death. Similar testimony is to be had concerning amputation, and Dr. Weir quoted from Bilroth's and Volkman's statistics, and also gave his own, all of which showed a very great reduction in the rate of mortality when compared with results obtained by old methods. In conclusion, the author of the paper repeated the words which he had used on a former occasion: "The saving of life which is thus indicated, occurring as it now does, or ought to do, ought to be enough to entitle the name of Joseph Lister to outrank in medicine all of his century, not excepting the discoverer of anesthesia."

Dr. A. C. Post was invited to open the discussion, and said he was convinced of the value of what is known as antiseptic surgery, although he was not fully prepared to acknowledge the necessity for all the details of the treatment which had been described by the author of the paper. There was no doubt that a vast improvement in the treatment of wounds had been obtained by Lister's method and its accessories; that is, great care concerning cleanliness, thorough drainage, and the use of antiseptic applications to guard against the morbid processes supposed to be assisted by micro-organisms. It had appeared to him, however, that in ordinary wounds, not involving very important parts, it was hardly necessary to go through the entire formality of these complicated dressings. As to the necessity of perfect cleanliness and drainage there could be no question. He was thoroughly satisfied that the results of antiseptic treatment, as carried out in the New York and Roosevelt Hospitals by Dr. S. S. and by Dr. Weir, had been so good as those obtained previous to the use of such precautions.

He mentioned one antiseptic to which reference had not been made, and which he had used in the treatment of minor wounds, such as small open wounds, and that was the subnitrate of bismuth, sprinkling the surface with the powder from a pepper-box, and then applying an ordinary dressing. All the wounds, so far, which he had treated in this manner had progressed remarkably well.

Dr. J. D. Bryant, since the spring of 1868, when an interne in Bellevue Hospital, had watched with great interest the development of the antiseptic method of treatment. Between September, 1869, and the spring of 1871 he treated twelve cases of compound fracture. He adopted the plan of treatment then best known, and simply injected into the wound a solution of carbolic acid, 1 to 120, thoroughly washed out all the nooks and crevices, washed the entire limb, and surrounded the whole with oakum saturated in a strong solution, 1 to 50. The limbs were secured in an immovable apparatus of plaster of Paris. Of the twelve cases described, ten had been recovered, and of these two, one was a particularly bad one, involving the ankle-joint with rupture of the posterior tibial artery and sloughing of the soft parts. Since the spring of 1871, when he left the hospital, he had used the ordinary antiseptic dressing as recommended by Mr. Lister. During the last few months of his hospital practice he had employed the bichloride solution, 1 to 2,000, in conjunction with iodiform, antiseptic gauze, quinacrine, etc., and with entirely satisfactory results, except in one or two instances, where the cause of the suppuration or rise of temperature could be traced to lack of attention.

To Mr. Lister undoubtedly belonged the credit of having perfected and introduced the antiseptic treatment to the profession, but the great fight which he had had with reference to eliminating external influences, as many, if not all, the other measures had preceded him. Dr. Bryant had full faith in the efficacy of the antiseptic treatment, and referred to two very severe cases in which its benefit was especially manifested. One was a case of very large sepsis with secondary infection, and a tumor of the parotid gland. He thought one of the things to be studied by hospital surgeons was how to simplify antiseptic precautions so that they might be brought within the reach of the general practitioner as to give the best possible results. At the present time the bichloride solution, with iodiform gauze, are probably the best that can be used. He employed catgut ligatures soaked in oil of juniper, and used short drainage-tubes rather than long ones, thus avoiding the possibility of the long drainage-tube acting as a foreign body in the wound. Dr. Bryant also reported a case which illustrated the great ability wounds sometimes exhibit to recover rapidly when subjected to ligature by catgut. The case was that of a large wound from a knife in which a very large number of ligatures were employed.

Dr. L. A. Stimson said there was more in antiseptic surgery than the mere antiseptic. He regarded it as essential to a fruitful discussion of the subject that a discrimination be made between the different parts of the problem. It should be recognized that there are at least two distinct parts: the first deals with the cause of the complications, which the dressings are designed to prevent; the second with the properties, the extent of the various dressings, and the value of each in preventing those complications. For a man who believes that suppuration or fever occurring in the course of the repair of a surgical wound is always the result of the introduction of germs from without the question is a simple one. It is his aim to clean the wound with an efficient
germicide, and to cover it with a dressing which will either filter out or destroy all other germs which may be brought to it. But for the man who thinks there may be some other cause; that these complications may arise through the perverted action of the elements of the body item, that they may be diminished, by some means. A case of nutrition, of tension, mobility, change of temperature, lowered or perverted vitality—for this man the problem is a much more complex one. He uses antiseptics to purify his wound, his own hands and those of his assistants, to purify his patient and his instruments, but after he has done that, after he has thus protected his patient from the dangers arising from one source, he has to employ other measures to protect him from those arising from other sources. He must have drainage, rest, and pressure, as well as cleanliness, and does not feel safe even then. There is still the unknown in the individual himself, that hidden fatal cause, whose action he can neither foresee nor avert, and it comes not only to him but also to the believer in antiseptics, and frequently enough to make that absolute confidence in their power to avert danger which men have recently expressed seem inexplicable, and action based solely upon that confidence rash almost to the verge of criminality. There is a great deal more in antiseptic dressings than the antiseptic itself, and each has many different properties, and the same properties may be used in varying degrees. The test of experience along a single line is not sufficient to decide the question between their respective merits. Brilliant results and disastrous failures have followed each and every one, and no single man's experience has been found sufficient to cover all possible variations of disease and dressings.

There are many things in antiseptic germs, only, leaving out all topical effects. It has been demonstrated, beyond question, that the introduction into the healthy body of certain germs will cause septicemia; and, therefore, the use of antiseptics to prevent such introduction is proper. But it has not been proved that the same disease cannot arise independently of such germs. Cases of apparently independent origin, cases of septicemia without external wound, are known to all of us. For example, he had a hospital case, that of a man who had fallen from the top of a house, injuring his ankle, but the skin was not broken, not even bruised. There was a small wound in the small of the back, and some damage apparently was done to the nerve-trunks, as shown by partial loss of the sense of touch. In the course of a few days, the foot and leg became swollen and crepitated; the limb was amputated, and found to be saturated with brown, offensive serum, gangrenous emphysema, and septicemia. There was no external wound, except that in the small of the back. The case could be explained on the germ theory in only one of three ways: The germs must have entered either through the skin, or through the small wound in the back, or through the lungs or alimentary canal. If through the wound in the back, then it would be necessary to dress every scratch, every pimple upon a patient's body. If they entered through the unbroken skin, a patient must be enclosed from head to foot in the dressing, the result being that then no patient is safe. It was much easier for him to believe in the spontaneous production of the septicemia, that it was due to some local change, perversion of nutrition, or defective innervation. It may seem unfair to compare such a case with wounds made by the surgeon's knife, but it seemed to him that surgeons did themselves injure wounds after operations, and that the result was the same, and thereby one of the principles of antiseptic treatment, that is, long-continued rest, is frustrated. By the use of the bichloride solution this disagreeable feature is avoided, as the bichloride leaves a very dry wound, does not dissolve the small clots which plug the vessels that have been cut by the surgeon's knife, and favors the leaving of the first dressing for a long time before it becomes necessary to change it. During the last six months he

tiseptics destroy germs, the use of the antiseptic method has been followed by good results, and, therefore, the good results are due to the antiseptics and complications are due to the entrance of germs. For many years we used carbolic dressings and got good results; and then we heard that carbolic acid evaporates and that the dressings we had been using were not antiseptic. Bichloride of mercury was substituted, and again with good results. Now Dr. Weir tells us that the bichloride is untrustworthy, for it changes into calomel. All this time, too, we have been putting catgut ligatures down in the bottom of the wound, and now we know that the carbolized oil in which the catgut was prepared is not antiseptic, that the catgut was sometimes actually rotten, that it contained the very germs we wished to keep out.

Again, putrefaction has been regarded as one of the sources of the trouble. Now, take one of the dressings the use of which has been attended with good results, namely, peat. It was thought to be in itself antiseptic, and was used without previous purification, and it gave excellent results. At the present time it is usually moistened with a bichloride solution. To test its antiseptic properties Dr. Stimson had made a series of experiments; he had saturated peat with a sterilized putrescible liquid, and within forty-eight hours the liquid was swarming with bacteria, while the liquid of the "cooling" box in which the peat was kept was full of germs. No one questions its value as a dressing, but its value must be due to something else than its supposed antiseptic quality.

There are many things in antiseptic dressings besides the antiseptic, and he believed that the good results which have unquestionably followed the use of these dressings were due to the other properties quite as much as to the prevention of putrefaction.

If the exclusion of germs is all that is needed, why should drainage be used, why should not every aseptic wound be transformed at once into a subcutaneous one by primary union of the skin? He mentioned a case to show how such an attempt fails. A simple fracture does not have drainage, and yet does not suppurate; but an open wound made by the surgeon and involving the bone will suppurate nine times out of ten, despite all antiseptic precautions.

While, therefore, he believed that the antiseptic method of treatment was exceedingly valuable, he also believed that the use of the antiseptic as a preventive of putrefaction after an operation on a wounded or injured limb is a restricted and limited one. He believed that by its use we only protect our patients from the action of specific poisonous germs, and that to it we must add other elements in the dressing. Free drainage must be established and perfect rest must be secured, together with equable compression and temperature. With the application of these principles, to the details of which it was not necessary to refer, he believed the patient was placed under the most favorable conditions for a rapid recovery to ensue. He believed, therefore, in antiseptics to purify the patient, the surgeon, the assistants, and the instruments, and then drainage could be comparatively used.

Dr. A. G. Gerster spoke of some of the points of advantage which the corrosive sublimate solution possessed over carbolic acid. It was well known that carbolic acid has a disagreeable effect upon the tissues, produces a bloody oozing which permeates the dressings very quickly, and necessitates a change of them within from ten to fifteen minutes; the results were unsatisfactory, and thereby one of the principles of antiseptic treatment, that is, long-continued rest, is frustrated. By the use of the bichloride solution this disagreeable feature is avoided, as the bichloride leaves a very dry wound, does not dissolve the small clots which plug the vessels that have been cut by the surgeon's knife, and favors the leaving of the first dressing for a long time before it becomes necessary to change it.
had used the bichloride solution almost exclusively in his service at the Mount Sinai Hospital, also at the German Hospital, and the essentials of the treatment were the same as those which had been related by Dr. Weir. It had been his desire to so simplify antiseptic treatment that antiseptic surgery could be adopted by the general practitioner. To this end he had been employing a material to which reference had not been made, and with excellent results—namely, common sawdust. After having the sawdust soaked for twenty-four hours in a watery solution of bichloride, 1 to 500, and then dried, it is put away in a tight box. Before each operation a suitable sized bag is filled with the sawdust, and under this dressing all his surgical cases had done as well as under the most aesthetical antiseptic dressing which could be imagined. He regarded iodiform as a very valuable dressing, and it could be used by sprinkling it over the ordinary gauze, or the sublimate gauze, where it would quickly form with the blood a paste substance, a protective more effectually excluding all external influences than any which he had seen. He also tried Spanish moss, but had not found it a very useful material so far as its absorbent qualities are concerned. It is exceedingly soft as a dressing, and does not absorb readily. The ordinary cotton batting had found to be a very valuable and excellent antiseptic dressing. He then referred to a case of compound fracture of the elbow-joint, occurring in an old man, with poor circulation and affected lungs. The ordinary cotton batting soaked in a bichloride solution was applied externally by the ordinary lint bandage manufactured on the spot from old sheets. The progress of the case was entirely satisfactory, the fracture progressed as though it had been a subcutaneous one; healing of the external wound occurred by first intention, and the case did very well. One reason why it did so, he thought, was that the cause of the injury was done to any of the more important blood-vessels, whereas it was quite possible in Dr. Stimson's case, referred to, such injury took place, and perhaps would explain the unfavorable result that followed.

He did not wish to enter upon the theory of antiseptics, but thought that all hospital surgeons admitted the importance of antiseptic wounds since they had been in use, in the strict sense of the word. Of course suppuration and fever had occurred in many cases after they had been used in the most careful and thorough manner, apparently so at least, but he thought the vigilant surgeon would find in time out of ten cases the cause of his failure, as he became familiar with general principles, and as he learned how, he was able to cope with them, would help to avoid subsequent failures. He then referred to a case in which he incised the shoulder-joint for the purpose of removing a portion of the capsule to prevent habitual dislocation. Elevation of temperature was present on the following day, and, without delay, he opened the wound entirely, found three or four catgut ligatures surrounded by pus, the remainder of them not being changed, and he had no doubt whatever that the catgut carried the infection into the wound. He believed that it is not germs alone which give rise to these unfavorable symptoms; the expression is too mild, since generally the complications are due to veritable lumps of dirt. He regarded continuous vigilance as one of the very essentials to the success of antiseptic surgery, and believed that in most of the cases which had proved failures, it had been said that the results were due to the fact that the spray was not used, or there was some other deficiency in the local applications, there would be found, on closer investigation, gross neglect with reference to cleanliness.

Dr. Weir, in the discussion, said he must agree with Dr. Gerster and also with Dr. Stimson, although both apparently took opposite sides of the question. Very many cases are treated according to the principles of antiseptic surgery which terminate unfavorably, but in the majority the reasons for their unfavorable progress or fatal termination could be found. At the same time he must say also that he had seen cases where he was unable to condemn or criticise the dressings or find want of care in their application, and yet evidence of septicemia developed. He did not think that as yet we have absolute control of all the elements in the cases, but so far the principles had led toward the perfecting of the method of treatment. Certainly he must not be rash, and he wished that he had seen cases with those who raised a voice of warning against undertaking certain operations which are hazardous to life and from which very little is to be gained.

With regard to bismuth, mentioned by Dr. Post, he thought that it did not prevent the occurrence of erysipelas, as most of the other antiseptic dressings employed seemed to do. The Academy then adjourned.

Correspondence.

SECOND-CLASS SHIP-SURGEONS.

To the Editor of the Medical Record.

Sir: Not two hours before the last issue of The Medical Record I had mailed a contribution to the London Times, which will appear on or about the 29th instant, and which seems so pertinent to your excellent article on "Second-Class Ship-Surgeons," that I take the liberty of handing you an unaltered copy:

"The Times recently published a letter by Dr. Domett-Stone, in which he does me the honor of quoting at length from my articles upon the present defective medical service on transatlantic steamers. I desire to add a few lines upon the channel through which this often disastrous condition of affairs may be amended. Dr. Stone advises the ship-surgeons to enroll themselves into a mercantile marine medical service with the view of laying their grievances before Parliament.

"Let me predict that the only result of such a movement would be the immediate dismissal of its leaders, and a probable increment of disability among those who survived the displeasure of their employers. Ship-surgeons are aggrieved; they are allowed no position or authority; they are assigned the worst cabins; they are remunerated on a par with cooks, stewards, and fourth engineers; in fact, their complaints are many and various. But who cares about ship-surgeons? People nowadays are tired of class grievances, and ready to accept what the general public can pass as results, quality, and both a normal standard of price; and that a class of workers driven to seek legislative protection are effective in the field of public usefulness.

"Let ship-surgeons who are dissatisfied with their position retire from it and enter upon any of the other walks of the profession which are open to them, and in which honest energy and ability are certain of ultimate recognition. Those who are content in a life of semi-indebitable dormancy may congratulate themselves upon the unique facilities for such an existence which the present system affords. But of this much all may rest assured, that even should the moiety of gentlemen and competent practitioners now in the sea services unite in a strike against existing conditions, such a course would not seriously inconvenience their employers.

"The average ship-owner desires a person whose qualification complies with the minimum requirement of the law, whose faculties or philosophy are of the character which accepts what is as right, who can be judiciously silent when it might be inconvenient to speak, judiciously blind when not determined to see, but who will ever be ready to act as a buffer between negligence and public indignation when the health interests of passengers come into opposition with the money interests of his employer. And unfortunately there are still in the profession
of medicine enough loafers and general "bad eggs" to fill the vacant posts, and render more homogeneous and quite as satisfactory to its employers a class in which the best and the worst are now exactly upon the same footing. Ship-surgeons must recognize that they are a drug upon an overstocked market, in which pertains the abnormal condition that the quality of the article is little object to the purchaser; and hence to grumble and formulate grievances must ever be a futile task.

"There is, however, another aspect to this question. It has been demonstrated that among the thousands upon thousands who annually cross the Atlantic there is a serious depression of health and a highly excessive mortality, referable to the unreliable medical service and the absence of an efficient sanitary administration on shipboard. Statistics collected from reliable sources, and unmistakably pointing to this conclusion, have been published by me, and still remain unchallenged, although proof has been offered for every statement which has been advanced. The British Medical Association has endorsed my views, and memorialized and interviewed the President of the Board of Trade, but as yet without result.

"Mr. Chamberlain, apparently absorbed in the matter of load-lines, and free boards, and unquestionably seaworthy craft, regarded it as a legitimate enterprise in one in which Government has no concern, that two thousand persons should be dispatched across this ocean in a steamer whose construction defies every law of sanitary science, and whose medical service is disgracefully inefficient.

"This, however, must soon come to an end, either with or without the intervention of the Board of Trade. If the profit interests of the transatlantic carrying trade are almost entirely European, the health interests of passengers are at least as much American. Of the saloon passengers by Atlantic steamers probably three-fourths are American, the steerage are with few exceptions already citizens of this country or intend to become such. The conduct of immigration has long since emerged from the legitimate sphere of private enterprise, and become an important national concern to this country. The United States has a distinct right to supervise the transit of her citizens; a right to follow the example of our British Colonial Government, who appoint an independent medical superintendent to every vessel carrying emigrants to their shores; and I do not hesitate to predict that unless reforms are soon instituted by the home authorities, Englishmen may prepare themselves, and that on short notice, to swallow an unpalatable pile of American interference in this important branch of British Trade."

I am, sir, your obedient servant,

J. A. IRWIN, M.A., M.D.,
Late Hon. Physician to the Manchester Southern Hospital for Women and Children.

365 Fifth Avenue, January 19, 1884.

Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 12, 1884, to January 19, 1884.

Buckwaster, W. B., First Lieutenant and Assistant Surgeon. Resignation accepted by the President, to take effect February 7, 1884. S. O. 10, A. G. O., January 12, 1884.

Official List of Changes in the Medical Corps of the Navy, for the week ending January 12, 1884.

Paxson, F., Surgeon. Detached from the Receiving Ship St. Louis on the 15th, and ordered to the U.S.S. Osseipee on the 22d.

Russell, A. C. H., Passed Assistant Surgeon. Ordered to the U.S.S. Osseipee on the 22d.

Eckstein, H. C., Passed Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, and ordered to the Receiving Ship St. Louis.

Wells, Howard, Passed Assistant Surgeon. Detached from the Naval Rendezvous, Philadelphia, and ordered to the Naval Hospital, Philadelphia.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending January 19, 1884:

<table>
<thead>
<tr>
<th>Cases</th>
<th>Typhus Fever</th>
<th>Typhoid Fever</th>
<th>Scarlet Fever</th>
<th>Diphtheria</th>

Phthisical Sputa on the Street.—M. Vignal has undertaken the rather unappetizing task of examining the sputa left by phthisical patients on the street, with reference to the presence therein of bacilli. He found the bacilli and states that, inoculated into two healthy guinea-pigs, tuberculosis resulted.

Drug Farms.—The plan of young doctors, unsuccessful doctors, and doctors with leisure on their hands cultivating drug farms has been suggested. There are doubtless many medicinal plants in this country which could be cultivated with profit, even on a small scale.

Stratified Statistics.—Dr. T. W. Grimshaw, Registrar-General of Ireland, has endeavored to find the different mortality rates in the different classes of society. For the first four weeks of 1883 the annual death-rate for Dublin averaged as follows: First class, professional men and those of independent means, 22.5 per 1,000; second (middle) class, 25.4 per 1,000; third class, artisans and petty shopkeepers, 26.1 per 1,000; fourth class, general service, 37.2 per 1,000; fifth class, inmates of workhouses, 37.2 per 1,000.

Copper and Cholera.—M. Thullier, the French scientist who died of cholera in Egypt, had been placed upon a copper regimen before he left France, and was continuing it when attacked with the disease.

Progress of the Proposed State Faculty Bill.—The Buffalo Medical and Surgical Journal states that very favorable comments upon the above bill are received from various parts of the State. It prints a number of these letters received by the Erie County Medical Society.

Supervising Medical Practice in Minnesota.—The first meeting of the State Board of Medical Examiners of Minnesota was held last month. Eleven candidates for a license were examined and seven passed. The board also passed upon about one hundred and seventy-five diplomas from different schools.

peculiar Micrococci in Cholera Infans have been found by A. Baginsky. They were present in the intestinal wall and in the dejecta. He also found numerous bacilli in these localities.
A SHORT SYNOPSIS OF NERVE FUNCTIONS.

By J. T. Searcy, M.D.,
Tuscaloosa, Ala.

In the light of modern physiology, we feel fully authorized in summarizing the functions of the nervous system under the general expression that they adjust action. This expression can be shown to include the whole range of functions, from the lowest centre to the highest brain. The intellectual cortex adjusts the individual to his environment, while the centres of the sympathetic, the cellular tracts of the cord, the medulla, and the lower brain adjust the actions of the parts and organs of the body to their surroundings. In a physiological consideration of these high orders of structure we need not engage in the more unsettled discussions of the day as to the manner in which these functions have been obtained or acquired. It seems to be a necessity of the times to accept the proposition as fully established, that the general or special use, object, function, of the nervous system, considered as a whole or in its several parts, is the adjustment of the manifold and various actions of the body. This is the characteristic feature of the centres, from their lowest to their highest grades; and the grades of adjusting action vary, like their structures, from the simplest to the most complex.

A centre or ganglionic tract of the sympathetic, of the cord, or of the medulla emits adjusting action along its efferent, outgoing fibrils to the parts over which it has control, that is, with which it holds efferent communication; and this emitted action is adjusted by the controlling centre to be in accordance with the action received by it, brought into it by its afferent incoming fibrils. The structures and functions of the lower centres are simple affairs in comparison with the immense complexity of structure and functions of the brain, still throughout, from lowest to highest, there are plans of action similar in all the different portions, varying only in grade. In the lower orders of centres the adjusting action is so simple and immediate that it has received the title of reflex action; higher in the scale we have automatic action; then there are instinctive acts; and finally we have intellectual action, or thought and reason. They are all adjusting acts and are the peculiar characteristics of nerve-centres.

I do not think the discovery of the circulation of the blood makes as important an era in the progress of medicine as the discovery of what we may style the circulation of the nervous system. The discovery of the sensory and motor nerves in the spinal cord was the initiation of it. The discovery that certain fibres bear currents of nerve action from the periphery to the centres, and others bear currents outward to the periphery, has led to much more practical and important results in the philosophy of the human system than ever have arisen from the discovery of the incoming and outgoing currents of blood. The discovery of one as much transcends the discovery of the other as the functions of the nervous system transcend the functions of the vascular system.

The fact that adjusting centres or tracts adjust the emitted acts to the received ones, leads very naturally to a division of such functions into the receptive, the adjusting, and the emissive acts. The adjusting act can be a very prompt and immediate one, or be a very complex and deliberate one.

Coming in to the median line from the two lateral halves of the body, the afferent centripetal fibres bring incoming currents of cellular, molecular nerve action to their adjusting centres or tracts. These adjusting centres are built up upon the terminations of these afferent fibres on the sides of the median plane opposite to or over against the incoming currents, and send back to the sides whence the incoming currents came their outgoing currents of adjusting action. Hence the decussation of fibres. There are also commissural fibres that connect the bilateral adjusting centres and render their adjusting acts simultaneous and harmonious—make the joint action.

In some low forms of animal life bilateral pairs of centres can be traced on both sides the median line, connected by fibres; each bilateral centre has a receptive part and an emitting part, separate and distinct from each other, and the adjustment is made by the two. Such distinction is not discernible in the structures of the human system, yet modern "localizations" in the brain point to certain tracts of the cortices from which the emitted efferent actions take their start, and other tracts into which the received afferent actions are poured; while the whole cortices seem to be engaged in the general adjustment.

The principal object in this manner of reviewing the functions of the nervous system is to make plain the general distinctive similarity in all its grades of action, namely, the receptive, the adjusting, and the emissive functions pertaining to all. All the centres have these three stages of action, no matter how simple or complex, how immediate or deliberate their adjusting actions are. Very naturally, next in this line of thought comes the question, What are sensations? I might very properly say they are the receptive acts of the sensing portion of the nervous system, and in the light of recent investigation I am warranted in saying that this high grade of receptive action lies in, belongs to, the cerebral hemispheres. Probably I had better say principally belongs to the cortices of the hemispheres, for as mentioned before, the receptive acts seem graded up to sensation: lower structures simulate sensation, have lower grades of the same sort of action, but practically speaking they are not sensations as the term is understood. You see it asserted recently that the sensing organ, the sensorium, is the cortical lamina of the cerebrum, which seems a correct statement.

More properly we ought to confine the term sensations to the receptive acts that are produced in the higher brain by the incoming currents of action brought to it along the afferent fibres whose distal extremities lie in the organs of special sense; by such currents of action, for instance, as reach these high sensing structures along the optic, the auditory, the olfactory, the gustatory, and the tactile nerves. Sensations then would be a term limited in extent, and would hold an intermediate position. Below them are all the receptive acts that do not reach the grade of sensations, and above them are grades of receptive acts that hold the high rank of intellectual perceptions. The symbols (of written or spoken language, for instance) that convey the abstract complex brain acts of one individual to another, it is true, only reach the brain through the channels of the special senses, but still very complex and abstract actions can be conveyed in
this way, and "concepts" of them produced in the brain of the second individual, provided he has a brain capable of performing that kind of action, which acts are grades higher and of another order than simple sensations, and still are on the receptive side. In other words, the perception of brain faculty is a grade higher than simple sensations.

I believe I am warranted here in the suggestion that not only the receptive acts of this high organ, the sensibility, are sensationed, but to use the term to convey the idea of a further advanced faculty or function, it is sensitive to its adjusting acts and its emissive acts also, which function or faculty is implied in the term consciousness. Consciousness, therefore, is a much more complex and a much broader term in its signification than sensation. The sensibility is therefore sensitive to, conscious of, all its receptive, adjusting, and emissive acts. The higher brain is conscious of its receptive acts (the sensations, the perceptions), of its most complex adjusting acts (thought, reason, etc.), and also of its emissive (voluntary) acts. It is tempting here to stray into the complex and entangled mazes of physiological psychology, but that is not the object of this discussion. The great majority of the acts of these high structures are phases of abstract deliberate adjustment, above the receptive sensation acts on one hand, and the emissary acts on the other, though the general plan of action holds here too of the receptive, adjusting, and emissive. There are ascending, transverse, and descending portions of the curve.

A great deal of confusion has arisen in the philosophy of the world by the consideration of the acts of the high sensations, especially in the brain, the hemispheres. The brain is, however, of an extrasomatic, metaphysical entity. Because the brain has the capacity of carrying its highest adjusting actions to a level above simple sensations and simple motions, therefore its functions have been considered those of a separate entity. It will simplify very much our understanding of the teachings and writings of the day that relate to the functions and faculties of the mind; for instance, why an act performed by an entity separate and distinct from the brain, if, wherever the term occurs, we substitute the word brain for mind. It is true, under this sort of a consideration, the sensibility becomes the ego, but we at once remove a great source of the delusion and confusion that is current on this subject, even in medical works. Thus qualified, it becomes a proper subject of physiological investigation. The brain, with excessively complex functions, is capable of being exercised, trained, developed, educated; and also, we readily see how it can be injured, disturbed, disordered, diseased, which is just as the facts of the case indicate.

The structures of the hemispheres of the cerebrum seem commensurate with the high functions assigned to them. Compared with the rest of the nervous system they are immense ganglionic masses. Connected by their pedicles with the upper extremity of the cord and medulla, they appear built up upon the incoming fibres that reach these high altitudes without adjusted action, or action from the special and secondary and tertiary, through these channels these actions from the opposite halves of the body, etc. The convolutions of these actions to these and formerly received acts (registered by functional morphosis). The results of the adjustment, which may have been an immediate or a most delicate and complex procedure, are emitted from this locality (motor tracts) along the outgoing fibres back to the opposite sides, and are exhibited in all the acts that constitute what is known as the conduct, the behavior, the speech, the deportment, the actions, the motions of the individual. Immense stretches of fibres in the "white matter" of the hemispheres connect the convolutions of adjusting "grey matter" with each other, and also, through the commissures and the corpus callosum, tracts of white fibres connect the hemispheres with each other, so that afferent incoming currents poured into the cortices in special localities produce receptive acts of the grade of sensations, and these (sensations) receptive acts at once become, through the multiplied connections, the property of all the consciously acting adjustment centres, by being in the rules and channels of adjustment; also through the commissural connections the adjusting and emissive acts of the two hemispheres are adjusted to each other.

In thus holding attention upon the functions of the high cortices, it will not do for us to lose sight of the direct connection and relation of their acts to the centres below. There is probably no line of demarcation where in the ascending scale receptive acts reach the grade of sensations, and no doubt disturbing, ascending, afferent action which lower centres are incapable of adjusting does go higher and may reach the grade of painful sensations; and, also, no doubt a great deal of frequently adjusted, repeatedly adjusted, action in the cortices under the rank of sensations, by repetition, in time becomes the work of lower centres. Such, indeed, seems to be the order of work of the cerebellum. It seems to fill the rank of the automaton. The immense amount of automatic work seems to require as much structural space as the cerebellum occupies. Intermediate in position, and largely connected with the incoming and outgoing currents of points particular to the sensory and motor action and by experiment, seems to hold this grade. It adjusts the automatic work of the body.

In the channel of the ascending afferent connections lie the optic thalami, and because of their adjusting action in the receptive line, they have had, of late, perceptive functions assigned them; but this grade of action is no doubt highly adjusted, the hemisphere in action—and by experiment, seems to hold this grade. It may be toward the cerebellum or toward the sensitising cerebrum. On the descending side also the corpora striata seem to hold similar adjusting functions, adjusting to greater or less extent the emitted currents.

Viewed as a whole the nervous system is a complete entirety. Its multiplied connections hold in united harmony all of the normal actions of the body, not only the actions of the various grades of centres, the various functions of the different parts. The centres equilibrate within the system the internal relations and they equilibrate without the external relations.

My object in this paper is accomplished if I have made any more plain the graded entities, the nervous system, and the general features of the receptive, adjusting, and emissive actions common to all centres.

By William P. Northing, M.D., Pathologist to the New York Foundling Asylum.

I had the pleasure of seeing the following case with Dr. J. V. S. Woolley:—

A patient, a man, thirty-five years, native of New York City; bookkeeper; single; temperate; without suspicion of syphilis. Has always been well and strong, except an attack of "inflammatory rheumatism" and "attacks of gall stones." The latter he describes as follows: Five times, in the last eight years, he has had at regular intervals, attacks of pain lasting two weeks. Pain was constant. He lost his appetite for a time, gradually diminishing. It was located first in the epigastrium, slowly extending downward to right hypogastrium. At each attack he was obliged to go to bed and was given morphine. His complexion was always "sallow." During the month previous to the present illness patient was not in usual health. He felt weak, lost his appetite. This condition gradually increased, until in the last two weeks he could scarcely drag himself about and regularly fell asleep at the table after dinner.
May 13, 1883.—While at his office he was seized with a sudden, severe pain, beginning in epigastrum, spreading in all directions. Pain was so severe he lay down on the office floor and groaned. On his way home in the elevated train he was obliged to stop off at three different stations and lie down, the motion of the cars so increased his pain. After a time the pain became intermittent, with half an hour's intervals being of such duration, and the pain controlled. After a few days the pain diminished and the patient seemed to be recovering.

One week from the first attack he was again seized with pain, this time located over the liver. There was prominence over the hepatic region, pain, tenderness, the edge of the liver distinctly felt at the level of the umbilicus, the pain was generally of dull, heavy, and distressing character, often severe enough to require morphone. Temperature ranged from 103° to 103½° in the rectum. It was at this time I first saw the case, two weeks from the beginning of the severe symptoms, and six weeks from the first recognized symptoms.

The following observations were noted: Patient confined to bed; consumption sallow; emaciated, drawn, anxious countenance; tongue heavily coated; moist; dyspepsia; moderate sweating; temperature, in the rectum, 103½°; hepatic symptoms as above described; bowels recently moved by cathartics; urine free of albumen and casts; no cerebral symptoms. Takes milk reluctantly. The tongue shows fluid on right side. A middle of the scapula, bronchial voice and breathing along the vertebral column; in the left lung exaggerated respiratory murmur, otherwise normal. Soon after this examination the patient informed his attendants that he was spitting up a large quantity of stuff that tasted and smelled horribly.

A permanent opening was at once made. In this case, on account of the free discharge of pus through the lung, it was deemed unsafe to administer anesthetics, fearing while under their influence the fistulized pus from the right side might flow into the left bronchus and injure the sound lung.

Patient was placed on his left side with the right elbow carried to the height of the forehead. For the incisions I followed the plan proposed by Dr. Francis Delafield, as follows: Place the patient as above described, find the first intercostal space below the angle of the scapula, follow this to five or six inches from the spine of the vertebræ, here making the first incision. Through this incision pass a strong curved steel sound downward and forward, and when after two months the hand finds the angle made by the diaphragm and chest-wall. Press its point firmly outward in the lowest intercostal space, and cut down upon it for the second opening. Through these two openings pass a large, fenestrated, rubber drainage-tube, the protruding ends of which may be conveniently held in place by large-sized safety pins. This method of operation is thought to secure the best drainage in both standing and recumbent postures.

In the present instance the first space below the angle of the scapula was followed to the margin of lattissimus dorsi, and the first incision there made. The opening was made first by cutting, the last tissues were parted by tearing. On puncturing the pleura there was a rush of most offensive gas, and at every effort of the patient a dash of fetid pus. On passing the sound downward to locate the second incision, to my amazement the sound pointed first about two inches above the umbilicus. The sensation conveyed was that the sound had passed into an irregular cavity, the whole liver is rotten with abscess, contains gas, and it was the relaxed diaphragm with its concavity upward, or a perforation. The answer to this must be sought in the history.

The second incision was made in the prescribed place. When the tube had been inserted it was found to pass out of sight about four and a half inches, its upper end in the eighth space and axillary line, its lower end about two and a half inches anterior to the upper, and owing to the obliquity of the ribs, passed behind but one of them. The discharge of pus during and just after the operation is estimated at four quarts.

Patient endured the operation well. He promised to lie still if allowed to "holster." He did both. For five days following the operation the case seemed very unfavorable. Temperature every four or six hours. Pulse was weak and small at once to 90-95° in the rectum; pulse was feeble; face "sallow," sunken, anxious; marked dyspnea; marked prostration. Could not speak above a whisper, and only a word at a breath. Hands and feet cold and moist; wounds both draining freely. Patient lay with head and shoulders raised and inclined to his right side. For nourishment he was given milk and water, and short intervals, prepared foods; later he was allowed to chew beefsteak, sucking out the readily soluble parts and rejecting the rest.

Strict attention was given to ventilation, but even then the odor was almost intolerable everywhere in the house. The dressings were at first oakum in large quantities. This had to be renewed four or five times a day. After two or three days the amount of exudate moderared. Carbolic acid was used, and the tube was washed out by syringing through. Carbolic acid, however weak and however applied, "burnt" him and was discontinued. Boracic acid and borated cotton, and salicylic acid were used and abandoned. The local treatment, then, for the most part consisted of a stream of water pouring through the tube twice a day, and changing the dressings of oakum or cotton cloths often enough to keep the wounds reasonably clean.

After five days the discharge running over the lips of the wound and skin caused widespread ulcers. These were very troublesome and painful. Iodine was sprinkled upon them and relieved the pain. This new odor upon the other caused severe and obstinate vomiting in two of the attendants and it was suspended. Cloths liberally smeared with zinc ointment afforded protection enough to allow the ulcers to diminish their diameters, but not to heal entirely. After two weeks the general condition of the patient had improved greatly. Appetite was fair, color of skin clearer, discharge from wounds less and not so offensive, strength gradually increasing.

At the end of four weeks patient was walking about the house, tube was removed, discharge only from sinus. Eight weeks from the operation, patient went to his desk and did part duty.

He came in the summer he suffered from symptoms of diffuse myelitis (diagnosis of Drs. Birdsell and Starr). After a vacation in the country of two months, he returned to his work in better flesh and general health than he had ever enjoyed before his sickness.

Seven months after the operation he was presented at Dr. Delfield's clinic, College of Physicians and Surgeons, and the following examination reported: No depression of thoracic wall at the site of operation. Otherwise the two sides are symmetrical. Percussion gives moderate dulness over whole right side. Vesicular murmur less distinct (distant) over same side.

Friction sounds about site of operation scars, nowhere else. Heart normal, possibly drawn a little to the right. The sallow skin which patient has had is no longer to be seen.

We have, then, a case of abscess of the liver and traumatic empyema, complicated by perforation of the lung and pneumo-pyothorax cured by thoracic drainage. Antiseptics were not used satisfactorily. I cannot but feel that a larger element in his recovery was the good stomach and indomitable pluck the patient possessed.

An instrument for the administration of anesthetics through the nose, in operations about the face and mouth, has been invented by Dr. B. C. A. Winder, of Birmingham, Eng.
From the preceding table (H) it appears that the greatest number of acute cases occurred between the ages of fifteen and thirty, and of this period the maximum number occurred between the ages of twenty and twenty-five. Thus the number of acute cases between the ages of fifteen and thirty was 143, leaving only 105 acute cases for all other ages; so that 56 per cent. of all the cases of acute rheumatism occurred between the ages of fifteen and thirty, and one-fourth of all acute cases occurred between the ages of twenty and twenty-five. It is probable that more cases of rheumatism occur in children than the preceding table would seem to indicate, since children are not as likely to be sent to a hospital, when attacked by rheumatism, as adults are to go when similarly affected. On this account the records show few cases occurring before the fifteenth year, although such cases are known to occur with greater frequency than the preceding table shows. In subacute and chronic cases only one case occurred (subacute) before the age of fifteen, and 14 cases between the ages of fifteen and twenty; the greatest number (27) occurring between the ages of thirty and thirty-five, the majority of these (23) being subacute. For any considerable period the greatest number of subacute and chronic cases occurred between the ages of twenty and fifty years.

### Table K.—Cases arranged according to maximum temperature in each case.

### Table L. — Comparison of the results in the treatment of rheumatism by different drugs, presenting duration of joint symptoms before and after entering hospital, of pyrexia after entering hospital, and of stay in hospital, arranged according to various methods of treatment, and subdivided according to maximum temperature, designed to show the comparative value of the different methods of treatment. All these are cases which left the hospital cured.

**Cases in which there was no Deviation from Normal Temperature.**

A CONTRIBUTION TO THE STUDY OF HEREDITY SPHILIS OF THE NASO-PHARYNX.  

By SAMUEL KOHN, M.D.,  
NEW YORK.

The diagnosis of hereditary syphilis is so frequently conjectural that any case in which the pathological changes admit of no doubt or question should be recorded; for it is only by this means that our positive knowledge of the subject may be increased.

The works of Jonathan Hutchinson, Von Bärensprung, Von Rosen, Lancereaux, Bäumler, and, in our country, Van Buren and Keyes, attest the difficulties of diagnosis, and the importance of an early recognition of the characteristic parenchymatous changes of this disease; and to us, as practising physicians, the study is of great interest inasmuch as it enables us to fulfil the causal indication in any given case, and thus to prevent suffering.

Cases of late hereditary syphilis in which timely treatment would have saved life have been reported; as it is not my intention, however, to go into an exhaustive study of the literature, which is extensive, I shall proceed briefly to relate the three cases which have come under my observation.

These three patients are children of the same parents, father and mother still living. The father is about fifty-five years of age, and remembers that when a young man, both before and after marriage, he was advised by his physician to take iodide of potassium for rheumatic pains from which he suffered.

Now let us look at the first patient, Heinrich G., twenty-eight years of age, pale, poorly nourished, protruding forehead, conjunctivitis. He has opsonia, the disease being slight, serous, and moderately ill-smelling. That which is of most interest is to be seen in the pharynx; the velum palate is adherent, throughout almost the whole of its extent, to the posterior wall of the pharynx; there is a small opening to the left of the median line, and quite low down, through which a small elastic catheter passes, when introduced through the left inferior meatus of the nose. The uvula is entirely gone.

The posterior wall of the pharynx is crossed and recrossed by dense, white, glistening bands of connective (cicatricial) tissue, which extend down to the osophagus, and scarcely a spot of healthy mucous membrane can be seen. The uvula binds the velum to the posterior wall, and on attempting to remove this mass the two, in order to facilitate nasal respiration, I found the tissue to be hard and gritty as cartilage; quite profound hemorrhage and the patient's struggles compelled me to desist from the operation. The isthmus fauces, and, in fact, the whole pharyngeal aperture, is contracted.

Such cicatrization is characteristic as the result of syphilitic ulceration, and the description given by Morell Mackenzie is so like the appearances here presented, that I cannot refrain from quoting what he says: "When the ulcerative process attacks both the posterior wall of the pharynx and the soft palate, the two surfaces may be brought together by the inflammatory tumefaction, and union of the opposing ulcerated surfaces sometimes takes place. . . . The isthmus of the faucial arch, and the velum, or whatever may remain of it, is drawn backward by white cicatricial tissue, radiating from the hard palate to the posterior wall of the pharynx. Sometimes the communication between the nose and the pharyngeal cavity is entirely cut off, whilst only a minute opening left at the lower part of the pharynx."

You will say that these cicatrices in a man twenty-eight years of age are due more probably to acquired than to hereditary syphilis. This assumption is negatived by his previous history; he states that as a child he never was well, suffering from moist eruptions and rheumatic pains up to his twenty-first year. He says further that he doesn't remember when he had a sore throat, and denies venereal disease.

Now look at Rosa C., aged seventeen, his unmarried sister. We find almost the same condition of affairs in her pharynx: complete adhesion of the velum to the posterior wall of the pharynx, so that breathing can only take place per os. When she awakes from sleep the tongue and mouth are parched.

No such glistening bands of cicatricial tissue are seen in this case, the union undoubtedly having been produced by superficial erosion of the two surfaces. It has even been claimed that such superficial erosions more frequently lead to a gluing together of the opposing parts than deep ulcerations. (Dr. Schecb, Deutsches Archiv für Kl. Medizin, 1876, Bd. xvii., No. 2 u. 3.)

The soft palate is so thin that the end of a probe introduced into the nose is felt impinging against it, by the finger introduced into the mouth. There is no cicatricial contraction.

This girl, to her own knowledge, has never been sick, and don't remember ever having had a cutaneous eruption. Nor is it possible that this adhesion of soft palate to pharynx existed during her infancy, because nursing would have been impossible under the circumstances, and matern in inanition must have ensued. The most probable hypothesis is that, about the age of puberty, a superficial ulceration occurred, without much pain, as is usual in syphilis of the throat, and that this led to adhesion.

In the case first related the destruction of tissue was deep, resulting in cicatrices, while in this one the erosion was superficial, and simply glued the opposing parts together.

The third case, Lena I., the married sister of the patients just spoken of, is twenty-three years of age, looks much older, is thin, poorly nourished, and anemic. She has one child about two and a half years of age, which is puny, sickly, and has corysa.

This patient suffers from ozena frigida. Examination shows the septum to be almost entirely gone, exfoliative necrosis of the vomer, and sinking in of the bridge of the nose. I have removed several necrotic pieces of bone. In this family there are four other children, the oldest thirty years of age, the youngest ten years of age, all so far apparently healthy, but what the age of puberty brings forth in the younger children remains to be seen.

The treatment of the three cases, so far as it was necessary, was antispetic and tonic, and has been attended by all the success which was to be expected. Of course the only method of loosening the adhesions is by the knife, and this we propose some day to attempt.

The points of interest in these cases are, first, that distinctively syphilitic lesions are present in three members of one family, who, since they never acquired syphilis, must have inherited the taint; 2d, that the only foundation, in fact, for our diagnosis, is the assertion of the father, that in his younger days he partook largely of iodide of potassium; 3d, the time of the eruption of the disease, which, in all three cases, is about the age of puberty, for such destructive throat disease could not be outlawed by an infant; or, on the other hand, had it occurred later than puberty, the patients would have remembered it; and lastly, that antispetic treatment has been beneficial. The cases are of interest, since they present to us for solution the problem of syphilis hereditary syphilis, in an acute form.

---

BUNSEN'S BATTERY.—A correspondent writes us complaining that he cannot keep his Bunsen cells in order. We can only say that the Bunsen cells are very little used now, and instead of attempting to make his battery work with them he had better get the Daniel or Leclanche cell.
Progress of Medical Science.

A New Theory on the Origin of Cancer.—Ever since the serious study of embryology began, the parts played by the time-honored layers of the germ of the embryo—the epiblast, mesoblast, and hypoblast—in the production of different systems of tissues have been looked upon by many as of an unalterable nature. And pathology has not been slow to take on the same principle of the exclusive origin of certain tissues from one lamina of the blastoderm. So it is that the epithelial origin of true cancer, so ably advocated by Waldeyer, is to-day the most prevalent view of the genesis of that disease. Numerous studies of different systems of tissues have been made, but no major transformation of units derived from the mesoblast has had, and still has, some able supporters. A fresh adherent to the views of Cornil and Ranvier in regard to this has appeared in the person of M. C. Sappey (Lancet, November 3, 1883). The results of his latest researches, communicated to the Académie des Sciences, are brought forward to aid cancer out of the recognized as resulting from a profound alteration of the leucocytes of the blood. This alteration is regarded as being at first essentially local. But whilst passing the primary focus of the disease, the white corpuscles of the blood become transformed, and may take one of three different forms. Some corpuscles migrate from the capillaries to the diseased focus, and become the cells by which the formation of a tumor which tends to increase without limit. Others are carried to the lymphatic glands, which soon undergo a secondary transformation. The third portion remains in the venous blood, and serves to propagate cancer more widely throughout the organism. Whether we consider cancer at its commencement, or in its course, or at its latest stage, it is always the blood-corpuscles which appear upon the scene and play the principal rôle. Such are the views of M. Sappey. He finds sufficient evidence in the following observations to warrant him in publishing the opinions given above. Examination of the blood drawn from the veins of an encephaloid tumor showed many leucocytes in the process of degeneration into cancerous elements. Leucocytes undergoing the same process were also to be found in the tumor itself, and similar changes were discovered in the circulation at large. We find it impossible, however, to concur with these latest teachings. The presence, in the venous blood taken from the neighborhood of a tumor, of leucocytes showing this process of modification, is to our mind of very doubtful significance, and certainly of but little importance. If the units were really cancer cells, of which we have our doubts, there seems to us to be no reason for supposing that they were derived from the leucocytes. It is not at all improbable that the white corpuscles of the blood do assist in the formation of cancers and other new growths not necessarily of inflammatory origin. But on such scanty data to postulate the doctrine that the leucocytes are the source of encephaloid cancer can only be regarded as an illegitimate exercise of the scarcely scientific imagination.

Belladonna in Nervous Dyspepsia.—Gallerani, following the advice of Lussana, has treated with success a case of nervous stomach trouble of two years' standing, accompanied by profuse pylaemia, by means of belladonna. He gave two-fifths of a grain of extract belladonna every four hours, before breakfast and after dinner, and the other an hour before dinner, during the first three days of treatment. This dose was increased to three-fifths of a grain daily during the last four days.—Rivista Clinica, November, 1883.

Syphilitic Neuralgia.—In a paper read before the recent Medical Congress in Freiburg, and published in the Deutsche Medizinische Wochenschrift of October 24, 1883, Professor Seeligmüller said that neuralgia of syphilitic origin was of much more frequent occurrence than is commonly supposed. Neuralgias of this cause have a particular localization. The painful pressure points are confined to a zone two or three finger breadths in width, passing from one ear to the other directly over the top of the head, like a round comb. The nerves concerned are the auriculo-temporal and lesser occipital. He distinguishes carefully between these neuralgias and syphilitic peripheral pains. The bones of the cranium, especially of the parietal bones. He relates a case in which a diagnosis of syphilis was made from the presence of this form of neuralgia alone, although there were no other clear signs of the disease and the presumption from the circumstances of the case was against it. In time other evid ent symptoms of syphilis were declared. Small doses of ars ule of potassium or of iron are a cure in his cases after all the usual remedies had failed.

A Ready Means for Cauterizing Poisoned Wounds.—Dr. Moser recently presented to the Paris Academy of Medicine a little invention of his which he called the crayon-feu, for ready use in the application of the actual cautery to poisoned wounds from the bites of venomous snakes, mad dogs, etc. It consisted in a little cylinder with sharpened extremity, enclosed in a case which also contained matches for lighting it. The composition of the stick is as follows: 15 small grains, 30 grams; nitrate of potassium, 4 grams; iron powder, 5 grams; benzoin, 1 gram; agglutinating powder, q. s.

To be made into forty crayons. These sticks are hard and burn readily and for a sufficient time to cauterize the wound.—Journal de Medicine de Bruxelles, vol. lxxv., 1883.

Anatomical Investigations on Bright's Disease.

Danin endeavors to explain the cause of Bright's disease and its relation to nephritis in general. There are two general questions which the considers must be answered first in order to approach the subject intelligently. 1st, Are all forms of nephritis one and the same malady? 2d, Where is the starting-point of Bright's disease; is it to be sought in degeneration of the epithelium or in the vessels or connective tissue? In answering the first question attention is to be directed at first to the chronic forms. These have been divided into two classes: 1, the so-called white kidney (nephritis parenchymatosu); 2, the granular kidney (nephritis interstitialis). A third form, the small white kidney, is considered as furnishing an intermediate stage between these two both in clinical and anatomical relations. His own studies have led to the conclusion that by these forms histological changes in all forms of Bright's disease are always of the same character, and that it is only, their combination which differs. These changes are: 1, swelling, destruction, and proliferation of the epithelium; 2, infiltration and new formation of connective tissue; 3, degeneration of the glomeruli; 4, thickening of the vascular walls. Even the amyloid kidney forms no exception to this, as in it all these appearances have been seen, and the amyloid degeneration is simply added to this. Such the author considers are the common phenomena of Bright's disease, and he then takes up some of the various forms of nephritis to see if they correspond or not. First, the forms which follow the acute infectious diseases. All authors are agreed that that which follows scarlet fever is to be regarded as a typical form of acute Bright's, and is to be placed in the closest relation to it. Of the other contagious diseases the kidneys of recurrent typhus are often to be placed in the same category, while those of typhus abdominalis are seldom so associated. In regard to the identity of all nephrites and Bright's disease: Professor Moser attempts to place between the large kidney with rather a finely granular look, which is related to the kidney of chronic passive congestion, and the so-called granular kidney of Bright's disease. The clinical picture is found to be different, and in the first case the microscope shows destruction of
the epithelium, collapse of the tubules, and an insignificant hyperplasia of the connective tissue. According to him, he has been taught about another: The epithelium is first attacked in consequence of an insufficient supply of blood (venous stasis, atheroma of the arteries, old age). This slowly proceeds, and the cells are floated off by the water, the lumen of the tubes remain patent for a time, and then finally the walls collapse. This is an apparent increase of connective tissue results. The vessels become dilated, and the organ presents the appearance of an angionia. In this there is no evidence of an inflammatory action, and therefore it must evidently be excluded from the class of Bright's disease. In Bright's disease, on the contrary, he considers that all the structural constituents of the kidney are affected at the same time. In this case, it should be called a "diffused nephritis." Since it is of this nature it is inflammatory, and its commencement is to be sought in changes in the vessels followed by an emigration of white blood-corpuscles into the glomeruli, the tubules, and the interstitial spaces. But how does the epithelium behave in all this? As is well known, its degeneration is constant, but in the greater number of cases this is retrogressive, and is to be referred to the same causal working that lies at the foundation of the inflammation; but, on the other hand, it is more frequently to be regarded as resulting from disturbed nutrition. So long as the whole process is confined to the disturbed nutrition of the epithelium simply there can be no analysis of the disease, and it is only when the action of inflammatory disturbances of the vessels has taken place that true Bright's can be said to have developed.—*Boston Medical and Surgical Journal*, November 29, 1883.

**Injections of Blood into the Pleural Cavity.**—Dr. Bernardino Silva relates in the *Rivista Clinica* for October and November, 1883, some experiments made by him upon animals to determine the amount of absorption of defibrinated blood injected into the pleural cavity. His experiments were ten in number, made upon rabbits, and led him to formulate the following conclusions: 1. Absorption of defibrinated blood proceeds through the pleura as well as through the peritoneum; 2. the effects of the injection of homogeneous blood (rabbits' blood used in all the experiments) are seen in an increase in haemoglobin and in the number of red blood-cells in the blood; five hours after the injection, and are prolonged for more than four days afterward; 3. the greatest increase in haemoglobin takes place within the first twenty-four hours; 4. the absorption of haemoglobin is greatest when the quantity of blood injected is small. If so much blood is injected as to produce atelecasis no increase of haemoglobin is observed; 5. the transfusion of blood into the pleural cavity causes an increase in the excretion of uric—an increase, however, which is preceded by a diminution during the first twenty-four hours. This last conclusion, the author says, needs further confirmation. In a note at the end of his article Dr. Silva states that Professor Bozzolo has made an analogous injection in the human subject, with beneficial results, in a case of anæmia complicated with malaria cachexia, ascites, anasarca, and albuminuria.

**The Curability of Locomotor Ataxia.**—The opinion has recently been expressed by Dr. Deboe that the sclerotic lesions existing in the spinal cord at the time when the lancinating pains are experienced, that is to say at the beginning of locomotor ataxia, preclude any hopes of curing this affection. In opposition to these views, Dr. Desnos affirms that there are cases in which the lesions existing in the posterior columns of the cord are curable. He relates a case of syphilitic tabes in which the pains were very severe and the inco-ordination marked, which was cured, at least all the symptoms were made to disappear, in five weeks by iodide and bromide of potassium with the protodiode of mercury. Dr. Cadiot has reported a case of undoubted locomotor ataxia in which the autopsy showed a simple congestion of the cord without sclerosis, and Dr. Desnos regards his case as one of that kind.—*Annales de Dermatologie et de Syphiligraphie*, November 25, 1883.

**Stretching of the External Nasal Nerve.**—Trousseau states that this operation is very simple and devoid of danger and is destined to replace, in certain cases, iridectomy and sclerectomy, succeeding often where these operations have failed. It often permits of the postponement or even abandonment of more grave operations, and where it fails it leaves the field open for other therapeutic measures. The operation consists in the excision of the stages of glaucoma, calming or preventing the pains, re-establishing, in greater or less degree, the acuteness of vision, and diminishing the intra-ocular tension.—*Rivista Clinica*, November, 1883.

**Pithiarias of the Eyelids.**—Dr. Santos Fernandez, of Havana, relates several cases of this affection observed by him in patients applying at his ophthalmological clinic. The parasite was always the *pediculus pubis*, which was found at the base of the eyelashes, which were covered with its nits. The symptoms of this blepharitis are an intolerable itching, worse at night, and, consecutive to this, an inflammation of the palpebral conjunctiva. The affection might readily be taken for a more grave disease unless a careful inspection by the aid of a lens were made of the edges of the lids. The treatment consists in the application of yellow precipitate ointment and a weak lotion of bichloride of mercury.—*Le Courier Médical*, No. 45, 1883.

**The Diagnostic Value of Thoracic Pulsations in Pleurisy.**—In a certain number of cases of pleurisy occurring on the left side of the chest, there may be observed pulsations synchronous with the action of the heart. These pulsations may sometimes be observed throughout a considerable extent of the inferior part of the thorax, sometimes they are limited to a small area in some portion of the chest where a fluctuating tumor exists, or in exceptional instances they may be seen in the lumbar region. In an interesting article on this subject in the November and December issues of the *Archives Générales de Médecine*, Dr. J. Comby states that these thoracic pulsations are due to a transmission of the cardiac impulse through the sclerosed lung and the superimposed layer of fluid. He says that they are met with only in cases of old empyema where the lung is contracted and adherent to the diaphragm; the pulsations of the left side where these pulsations exist the fluid is purulent. The pulsations indicate the presence of pus, and not only this, but they are a sign that complete and incurable retraction of the lung has taken place.

**Caustion of the so-called Autopomia.**—While it is conceded that autopomia, *i.e.*, the very annoying, loud, trumpet-like resonance of one's own voice or breath-sounds, occurs from patency of the Eustachian tube, an explanation has been hitherto wanting of this symptom in cases of cases of autophonia with obstructed tubes. Since a stopping up of the tubes is not of itself able to give rise to autophonia, Dr. Brunner thinks to explain its occurrence in these cases in another way. He says that the inflammatory swelling of the membranous walls of the tubes of recent otitis media prevents the easy falling together of the walls and consequent valve-like closure. If the walls are pushed into the lower third of the tube, it will resound in the ear although the upper part be plugged up.—*Centralblatt für Chirurgie*, October 17, 1883.

**Nephritis from Compression of the Ureter in Cancer of the Uterus.**—In an article published in the *Revue de Médecine* for November, 1883, Dr. Artand relates at length the post-mortem findings in several cases of cancer of the womb, in which one or both ure-
ters were compressed or obliterated by the neoplasm. There was secondary nephritis from this cause, with either hypertrophy or atrophy of the organ, and further, an hypertrophy of the left ventricle of the heart. His investigations led him to conclude that compression of the renal vessels in the case of uterine carcinoma gives rise to renal lesions of varying severity, depending on the duration and degree of obstruction. When the compression is but slight, the kidney is of normal size or slightly increased. The histological lesions in these cases consist in a nuclear infiltration around the ureteric tubules and vessels (glomeruli and arteries), an hypertrophy of the kidney itself, and a condensation of the epithelium whose epithelium has undergone a granulo-fatty degeneration. The straight tubules have very nearly their normal diameter, and the epithelium lining them is apparently unaltered. This he calls the first stage. When the compression has existed for some time, the ureter and the pelvis of the kidney are greatly distended, and the kidney itself is atrophied. The degree of atrophy is in direct proportion to the distortion of the ureter and pelvis. The histological lesions consist in a change to a fibrous condition of the primary nuclear infiltration, and a collapse of the straight tubules, whose epithelium has undergone embryonic degeneration. The glomeruli are either fibrous or cystic. The convoluted tubules present the same character as in the epithelium as in the first stage. This is the second stage. These lesions resemble those caused by ligation of the ureters in experiments upon animals. They differ from the latter, however, in that they constitute an acute diffuse nephritis, in the development of which the inflammatory element plays the chief rôle. On the other hand, it is the mechanical element that is most prominent in the lesions following the aseptic ligation of the ureters. These kidney lesions, following upon compression of the ureter from cancer of the uterus, are very frequently accompanied by hypertrophy of the heart, confined exclusively to the left ventricle, and scarcely ever accompanied by interstitial myocardiitis.

THE INCOCULABILITY OF CANCER.—Various experiments have been made to determine whether cancer can be transmitted from one individual to another by means of inoculation. These may be divided into four classes: The inoculation of “cancer juice” beneath the skin; injection of cancerous matters into the stomach; injection of the same into the blood-vessels; and the transplantation of cancer by grafting. Experiments made by the first two methods have given negative results, while in certain cases tumors have been developed after the injection of tissue in the subcutaneous layer. The logical examination has not determined their cancerous nature. Attempts made to transmit cancer from man to the lower animals by grafting have been unsuccessful, and the results obtained by grafting from one animal to another of the same species have been doubtful. It would seem, however, when the recipient of the graft is already affected with cancer, or predisposed thereto, that it is possible to transmit the disease in this way. In the Revue de Chirurgie for November, 1883, Dr. Nicaisse relates a case in which a secondary tumor was developed at a punctured point in a case of sarcoma of the uterus. He concludes, from a study of the various experiments and clinical observations, that the transmissibility of cancer from man to men in their afflictions in the first person to another of the same species, is not proven. But in the human species, sarcoma, under certain conditions, is capable of being developed secondarily in the same individual by grafting, and the same is true concerning certain papillary tumors of the ovaries.

SALICYLATE OF BISMUTH IN THE TREATMENT OF Typhoid Fever.—Dr. H. Desplats has treated a number of cases of typhoid fever with salicylate of bismuth (one part of salicylic acid to two parts of bismuth) with very satisfactory results. Even in the height of the disease the effect of the remedy upon the temperature is very evident. From 75 to 90 grains a day caused a reduction of temperature of about 5° F., beginning soon after the administration of the remedy. A larger dose than this was seldom given. When the drug was given continuously for several days, the reduction of temperature became permanent. The patient suffers at the onset of a considerable loss of flesh, but they often recover saw any dangerous degree of weakness occur. The remedy has no apparent influence upon the other symptoms, though in certain cases it seemed to have an abortive effect upon the disease. Dr. Desplats prefers it to the sodium salt, as it is less soluble, and probably on that account is less quickly excreted. Centralblatt für Klinische Medicin, November 17, 1883.

ARTICULAR AND OSSUSOS CRISES IN THE FOOT IN LOCOMOTOR ATAXIA.—A peculiar deformity of the foot, occurring in the course of tabes dorsalis, has been recently observed by Drs. Charcot and Fétre. The same affection has also been described by Page, in the British Medical Journal for the current year. The inner border of the foot, opposite the scaphoid and first cuneiform bones, is arched forward, while the metatarsus is bent outward as if it were luxated, presenting a sharp angle at the first tarso-metatarsal articulation. There is no inflammation, no pain, no crepitus. At the autopsy of a case of this kind the following changes were noted: The under-joint surface of the astragalus, as well as the corresponding part of the os calcis, were torn away and presented dissected vegetations along their edges. The whole foot was fractured at the neck. The scaphoid and cuboid bones were greatly deformed. The first cuneiform bone was very large, and it and the second were anchylosed with the corresponding metatarsal bones. The third cuneiform bone was broken into numerous fragments. All the tarso and metatarsal bones were spongy, soft, and lighter than normal. These observations are as yet without any supplement of any traumatism, and had nothing to do with any supplicative processes. The autopsies showed that they were analogous to the lesions occurring in the long bones and larger articulations in locomotor ataxia. Centralblatt für Klinische Medicin, November 10, 1883.

INTESTINAL WORMS AS A CAUSE OF INVAGINATION.—In a number of autopsies practised upon animals dying with spastic constipation of intestines, Dr. H. M. was able to find in a certain number that the obstruction was due to intussusception. In nearly all these cases he found a large number of ascarides in the intestine, and thought that the irritation caused by their presence had induced such energetic peristaltic movements as to force a portion of the small intestine through the cecal valve. The very acceptance causes, the imperfect hygiene and enteritis, and it is probable that the intussusception in these cases was referable to an enteritis set up by the presence of large quantities of the lumbricoids, rather than to simple irritation. Revue Médicale, December 1, 1883.

TREATMENT OF BROMIDROSIS OF THE FEET.—Dr. Viesse claims to have obtained excellent results in the treatment of this affection, whether there is a simple hyperperspiration of the feet or there is also severe pain, by frictions of the part with substrate of bismuth in powder. Contrary to the general opinion, he never fears and has never seen any evil results following upon the rapid suppression of the hyperidrosis. The substrate of bismuth seems to have a purely local action, rendering the skin harder and more resisting. The drug probably also exerts some influence over the sudoriferous glands and sebaceous follicles, changing the quality and quantity of their secretion. Its action might also be due to some modification in the subcutaneous capillary circulation. Sometimes the substrate of bismuth causes only a temporary relief in hyperidrosis, but it cures permanently the bad odor and the tenderness of the feet, which are the chief causes of complaint in this affection. Revue Médicale, December 1, 1883.
THE MEDICAL RECORD:

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, February 2, 1884.

SPECIALISM IN THE COUNTRY.

The increase of specialists and of special departments in medicine is the most prominent feature of the medical history of to-day. The attendant advantages and dangers have been often and variously discussed. Those who are dolorously inclined assure us that in the general practitioner will become merely a sign-post to point out the specialist, who has himself become only an artisan in the diseases of his chosen organ. Those of happier mind see in the growth of specialization and the division of labor a bright promise of the more rapid advance of medical knowledge to the position of a veritable science.

Without discussing now the merits of these two views, we would call attention to a particular phase of the specialization movement, viz., the gradual appearance of specialists in the smaller cities, large towns, and even in the well-populated rural districts of the United States. We have often been reminded by contributions received of the existence of this fact. In a city of fifteen or twenty thousand inhabitants or over in the East, in some parts of the West, and to a much less extent in the South, one or more physicians may often be found who devote themselves especially to ophthalmology, gynecology, laryngology, or some other department of medicine. These are generally young men who have passed some time in special hospitals, or have studied special courses in the large cities of Europe and America. Their dissemination throughout the country is a mark of the decentralizing process which is, to a certain extent, affecting medicine as well as many other things. For at the present day with the abundant means existing for rapidly diffusing knowledge and skill, a monopoly in these things at least is impossible. No physician or surgeon possesses therapeutic resources or technical skill beyond what others can gain. And it is the ambition of many of our younger medical men when graduating to learn not only that which fits them for general practitioners, but to obtain additional skill in some special branch. Every year there go out into practice, therefore, a considerable number who have some special as well as general equipment for their work. It cannot be said that these provincial specialists meet with a great and flattering success. Indeed, they have many difficulties to encounter.

If they attempt a general as well as special practice their medical brethren are apt to be jealous; and we have heard that they not only refuse to ask them in consultation but send to the large cities cases which could be perfectly well treated by their colleague at home. On the other hand, few can afford in provincial centres to devote themselves to a specialty alone.

Notwithstanding such obstacles there is and will continue to be a diffusion of special medical skill through the country. And it cannot but have a beneficial effect. It is a stimulus to general practitioners, and is undoubtedly helpful to the public, many of whom cannot afford to go to cities for special treatment.

The general practitioner will also learn in time a few things which he does not seem to be able to comprehend now. One of them is that two-thirds, perhaps, of the professional work done by specialists could just as well be done by general practitioners, if they would have the patience and foresight to equip themselves for it. We mean, for example, that by diligent application for a short time, with good clinical advantages, they could learn to treat with a specialist's skill the ordinary run of diseases of the throat, skin, eye, nose, uterus, etc.

On the other hand, while none but a genius can be an "all-around specialist," it is not impossible for a physician to be skilful in several branches. Perhaps this fact will in time help provide specialization. At any rate, we are glad that it exists, and in the interests of the whole profession shall encourage its growth.

CHOREA AND RHEUMATISM.

The much-vaunted question of the relation between chorea and rheumatism was made the subject of discussion at a recent meeting of the Neurological Society and was well discussed by Dr. Chapin, in a paper read at that time and printed in The Record. Some new statistics were added by the participants in the discussion as well as by the author of the paper. We call attention to the matter, therefore, for this reason, and because coincidently Dr. Octavius Sturgis has published a contribution to the same subject in the Lancet of November 10th. Dr. Sturgis is already known for his previous studies of this question, by which he has been led to the conclusion that rheumatism is not the important pathological factor in chorea usually supposed. In his present paper, he gives analyses of 70 cases of chorea admitted to the hospital for sick children, Great Ormond Street, London. He gives the following results of his analyses of these, and of his 132 previous cases:

Of the 70, eight had had rheumatic fever previously; ten had some form of rheumatism previously; one was doubtful on this point. Comparing these figures with the 132 cases previously given, it will be seen, he says, that in the latter number there were seven who had had rheumatic fever; fourteen or fifteen who had had rheumatism; six doubtful; five not ascertained. Thus 202 cases yielded fifteen who had had rheumatic fever; twenty-four or twenty-five who had pains supposed to be rheumatic; and twelve doubtful or unknown. "We have thus, on a review of over 200 cases, a percentage of acute rheumatism of 7½, and a percentage of joint pains, presumably rheumatic, of about 12; or grouping the two together, we have 19 per cent.—say one in five—of choreic patients (children) who have probably had some form of rheumatism."

The above makes the proportionate number of rheu-
mastic histories in cases of chorea considerably less than is usually given. Some of the statistics relating to this subject may be seen in the accompanying table.

The great difference in the results obtained, as indicated by the above figures, shows that there are serious difficulties in the way of obtaining exact information upon this matter. The histories of these cases have to be extracted from those who are non-expert and who are often ignorant and stupid. Dr. Sturges refers to this fact, and has taken especial pains to make his inquiries with care and exactness.

It has been suggested that the per cent. of rheumatism among children under fourteen or fifteen years of age belonging to the poorer classes, from whom most of the statistics are collected, is in all cases large. The general opinion, to be sure, is that rheumatism is rare in children, an opinion which Sée has given strength to by his investigations. He found that among 11,500 children received into the Children's Hospital at Paris, there were only 48 cases of rheumatism without chorea, while there were 61 cases with chorea. This proportion is so different from the experience of others that we are inclined to doubt the trustworthiness of Sée's statistics altogether.

Sturges has studied the matter with care, and states that the normal proportion of cases of rheumatism among persons received as hospital patients cannot be less than 15 per cent. for children and 20 per cent. for adults. In order, therefore, for the per cent. of rheumatic histories in choreic children to be above the normal, it must exceed 15 per cent. His own statistics show that the rheumatic cases but slightly exceed this average. Other statistics have shown that rheumatism is more frequent in boys, while chorea is four or five times more frequent in girls. The evidence at present thus compels one to be careful in ascribing too close a connection between rheumatism and chorea. There is undoubtedly some relation between the two diseases, but its exact nature is a problem for the future to solve.

THE RUGBY GAME OF FOOT-BALL.
In his recent report, President Elliott, of Harvard, has called attention to the subject of college athletics, and particularly to the subject of the Rugby game of foot-ball. It is stated that the foot-ball eleven of a leading college set out for its last contest with eight substitutes and a surgeon. The accounts in the public press show that few public games occur without two or more persons being laid up for a time at least. It is not very surprising, therefore, that the Faculty of Harvard College has, for the above and other reasons, forbidden its students to play the game until some modifications of the rules have been made.

It is a misfortune that a number of our most popular sports have been made either too difficult or too dangerous for any but the most robust and skilful to indulge in. We learn that in some of our smaller colleges foot-ball is nearly abandoned because the old game is "old-fashioned," and the new game is only adapted for heavy weights. There are yet no statistics to show to what extent the Rugby game is seriously dangerous to life or limb, though fatal accidents have been reported in English journals.

It is, however, a perversion of the true end of "manly sports" to make them intrinsically difficult and within the reach of but a vigorous few. In the Rugby game of foot-ball, the person, not the ball, is made the point of attack, and the rules are therefore radically defective, looked upon from the point of view which we, as conservers of bodily health, must take.

Foot-ball, as formerly played, was one of the most invigorating and manly of sports, and one which almost any one could to some extent indulge in. The question seems to be whether Anglo-mania shall be allowed to restrict the usefulness and pleasure of which the American game was a source.

THE THERAPEUTICS OF MALARIAL DISEASE.
It is well known that quinine sometimes fails in the treatment of intermittent fevers, both regular and irregular. This sometimes depends upon its mode of administration: it is soluble in acids; insoluble in alkalis. If given only when the stomach is empty, the alkaline mucus of the stomach will render the quinine insoluble, and large quantities will be taken to little advantage. But if acids be freely used in conjunction with the quinine it will all be kept soluble and active. Lemon-juice, which is a citrate of potash, is not as good as citric, phosphoric, or tartaric acid, all of which, like most acids, are not only good germicides, but good solvents of quinine. Again, ever since Bence Jones discovered animal quinoidine in the healthy human body, it has been suggested that the persons most subject to malarial diseases are deficient in this important ingredient. Unless we can force or teach these backward constitutions to make their own quinoidine in sufficient quantity, we must perhaps supply it by oft-repeated doses, which, after all, is not a perfectly satisfactory way. Still it is a useful and convenient one.

Again, as quinine is rapidly eliminated by the kidneys, considerable quantities appearing in the urine in three hours after it is swallowed, and all being thus removed in the course of two days, repeated doses are absolutely essential; and we thus can understand why relapses after the partial and interrupted use of quinine so often take place.

But frequently something else besides the absence of the assumed normal quinoidine in the body of the patient prevents the full action of quinine. Among these, what is called biliousness often obstructs it. As bile is alka-
THE MEDICAL RECORD. [February 2, 1884.

line, an excess of it will, of course, interfere with the solubility and activity of quinine.

It is easier to sweep out a large quantity of bile, when it has got into the bowels, than it is to prevent its excessive formation; and for prompt palliative action it is better to do so. Rochelle, Epsom, or Glauber salts, either in simple solution or in one of the many mineral waters, like Hunyadi, Friedrichshall, Pullna, etc., are very good, especially if a little sulphate of iron be added to each purgative dose.

Aloes is also an excellent remedy; the main efficacy of Warburg's tincture depends upon the large quantities of quinine and aloes which it contains; but one or two pills, of two grains each, of extract Soocotrine aloes and resin of jalap, will carry off all the bile they find in the bowels, and then quinine and aloes may be given alone.

Gastro-intestinal catarrh, duodenal catarrh, and catarrhal jaundice, with the large quantities of alkaline mucus which attend them, present very serious difficulties to the absorption of quinine. Blue pill, or a few grains of calomel, will meet this indication temporarily, especially if followed by the acid, or pyro-phosphate of soda, or by muriate of ammonia.

But marsh malaria, as we often meet with it, does not come solely from vegetable decomposition, for a more or less animal element is too often combined with it. To say nothing of the small insects, worms, reptiles, etc., which die in large quantities with decaying vegetation, there is often sokeage from privies, manure pits, drainage from kitchen sinks, and exhalations from obstructed house-drains. Again, to the borders of marshes, ponds, and sluggish streams, much house and stable refuse is apt to find its way. Then, what for want of a better term we call a typho-malarial disorder, arises, frequently so regular or so marked that it is often supposed to be purely miasmatic malarial; yet it withstands quinine. Some of these cases will yield at once to arsenic, sometimes aided by quinine and sometimes not. Carbolic acid is probably useless, but iodine is often available, and also bromine.

The consequences of the long-continued action of malaria upon the blood are disastrous. It loses its red globules, while the white diminish in size and increase in number; the liver and spleen may enlarge, the stools become clay-colored, and the urine may contain albumen or be deeply colored with bile pigment. Iron and aloes meet this indication; either equal parts of wine of iron and tincture of aloes, or sulphate of iron and aloes, or sulphate of quinine with sulphate of iron, with or without aloes, all in pill form. The iodide of iron is a good remedy.

The essential oils of cloves, peppermint, mustard, pepper, eucalyptus, etc., are good malaricides. The peppers, mustard, and cloves can be used freely as condiments; and table salt is not to be despised; it is decomposed in the stomach, and its muriatic acid goes to reinforce the gastric juice.

We throw out these suggestions for the consideration of our learned and ingenious readers, many of whom may be able to improve upon them.

The deeper and more complex forms of town and house malaria, which Dr. J. C. Peters has so aptly called civic malaria, made up from the exhalations of obstructed underground watercourses and drains, sokehage from gas-pipes or sewer mains, leakage from badly paved streets and gutters, and various nuisances in houses, will be discussed at another time.

INSANITY AS AFFECTING A LIFE INSURANCE POLICY.

An important case on the question of insanity as affecting an insurance policy which excepts the company from liability in case of suicide, and the insane person kills himself, has recently been passed upon by the Supreme Court of the United States, and is of great interest as showing the progress of medical and legal opinion on this point. It has been held at various times that if a person kills himself in a moment of frenzy, and his policy excepts death by suicide, he cannot recover. Such is not, however, the general ruling of the courts, and now our highest judicial tribunal has affirmed the broader and more liberal opinion. The rule is thus stated: "A self-killing by an insane person understanding the physical nature and consequences of his act, but not its moral aspect, is not a death by suicide within the meaning of a condition in a policy of insurance upon his life, that the policy shall be void in case he shall die by suicide, or by the hands of justice, or in consequence of a duel or of the violation of any law." The testimony as to insanity is thus summed up: "Members of his family and persons well acquainted with him in his business testified that he was naturally of a lively, cheerful, sanguine disposition; that in 1874 he met with heavy losses in business, and his son died suddenly by falling from a window; that from that time forward there was a marked change in his demeanor; he was always walking with his head bowed down and a gloomy expression, and the entire vitality and cheerfulness which the man had before was gone; he was gloomy, dull, morose; he sat down in the office and moaned and would be gloomy there; he always complained of his head; he would say "the trouble is here, it is all in my head, my head," that shortly before his death he had a vacant expression in his face; he had a queer expression about his eyes; it was a sort of wild, unnatural expression; that kind of expression which the human face takes on when one is frightened, a far-off, glassy look, as though the mind was dwelling on nothing; he was very much changed and was very excitable, he looked very different and had a wild expression, he staid a great deal by himself when he came home from business, he would go to his room and lie on his bed with his hat and overcoat on, and not come out to his meals. The experts called for the plaintiff testified that he was suffering from that kind of unsoundness of mind which they termed melancholia."

Upon this testimony the jury decided that the plaintiff was insane, and the Court decided the legal inference to be that if his "reasoning faculties were so far impaired that he could not fairly estimate the moral consequences, the moral complexion of the act, even though he could reason sufficiently well to prepare with great deliberation and to execute his design with success, nevertheless he was so far insane that the plaintiff is entitled to recover on this policy. If a man's reason is so clouded or disturbed by insanity as to prevent his understanding the real nature of his act, as regards either its
physical consequences or its moral aspect, the case appears to us to come within the forcible words uttered by the late Mr. Justice Nelson, when Chief Justice of New York, in the earliest American case on the subject (Breasted v. Farmers' Loan and Trust Co., 4 Hill, 73, 75), speaking legally also (and the policy should be submitted to this test), 'self-destruction by a fellow being of reason can with no more propriety be ascribed to his own hand than to the deadly instrument that may have been used for the purpose,' and whether it was by drowning, or poisoning, or hanging, or in any other manner, 'was no more his act, in the sense of the law, than if he had been impelled by irresistible physical power.'"

A STATE BOARD OF MEDICAL EXAMINERS.

The resolution offered by Dr. Sturgis at the last meeting of the County Medical Society involves more important questions than appear at first sight. To ask the Society to endorse any particular bill, no matter from what source it emanates, which has for its ultimate object the creating of a Board of Examiners who shall decide concerning the qualifications of all those who desire hereafter to begin the practice of medicine in this State, is allowable; but we believe the Society acted wisely in not further committing itself to any plan than it did by the adoption of the judicious substitute offered by Dr. Roosa.

The profession throughout the State is well aware that the proposition to create a State Board of Examiners is not new, and is one upon which there has already been expressed a great diversity of opinion. Previous discussions have developed the fact that the interests involved are so numerous, the rights liable to be invaded so well established, the friends of any measure cannot reasonably expect to obtain for it the endorsement of the profession until it has been discussed and so matured that conflicting opinions will in the main be reconciled. To accomplish this it is essential that, however desirable the ultimate end to be gained may be, all action should be subjected to the most careful scrutiny before any proposition is accepted.

Moreover, there is grave doubt concerning the propriety of the Committee on Legislation of the State Medical Society asking that their plan be endorsed by County Medical Societies before being submitted to the body which empowered the Committee to act. The subject-matter of the resolution belongs legitimately and primarily to the State Medical Society, and doubtless will be one of the topics brought up for discussion at the coming annual meeting.

HIGHER EDUCATION AND THE MEDICAL COLLEGE OF VIRGINIA.

There are in the United States one hundred and twenty medical colleges. Of these only twenty-seven require three courses of lectures; only thirteen have a term of more than twenty-four weeks, and the number which really insist upon a sufficient preliminary education is extremely small. These colleges have over twelve thousand matriculated students, and every year graduate over four thousand men, who, for the most part, start out at once to join the ninety thousand doctors already in the land. The number of medical colleges and of medical practitioners in this country is disastrously excessive.

It is for this reason that we have chosen on every proper occasion to criticise the medical colleges which continue to supply an unfelt want, by graduating after two courses of lectures men who have been subjected neither to rigid preliminary examinations nor careful practical training in hospital wards.

It was in accordance with what we considered were the best interests of the profession that we criticised the Medical College of Virginia. The main charges were incompetent clinical instruction and training, things which can but occur in colleges which exact neither three courses of lectures nor a high standard of preliminary education.

We have received a courteous protest from the faculty of this college, claiming that our remarks were founded upon misapprehension and imperfect information. We must decline to publish the letter in full, since it adopts the policy of refusing charges by berating its critics. We are, however, anxious to do the faculty full justice, and we cheerfully admit that the reputation of the college for careful didactic teaching cannot be impeached.

We cannot withdraw what we have said, however, as to the main issue, for our accusations were made advisedly and after due consideration. The college, by its own confession, exacts no preliminary examinations unless it sees fit.

Its course consists of terms lasting twenty-four weeks, and its catalogue does not state that it requires students to study medicine even two years. Students are required to disent for only one session, and in a special announcement the faculty offer to lend a "helping hand" to those "whose circumstances render them unable to meet the usual pecuniary obligations"—a sentence which in these days has a wide significance.

Let the Medical College of Virginia place itself upon the plane of higher education if it wishes to escape criticism. The country does not need more doctors, and the colleges which turn them out on the short-course plan are actually injuring the profession and society.

THE NEW YORK POLYCLINIC.

If evidence were wanting to prove that in the education of medical students in American colleges a more thorough clinical and laboratory course of study was demanded by most graduates, and among these the better class of practitioners, this evidence would be found in the perusal of the quarterly circular announcement of the institution the name of which forms the heading of this article.

It cannot fail to gratify the pride of every medical man who looks forward to and is courageous enough to insist upon a higher standard in medical schools, to see in the rapid growth and success of the idea represented in this institution a rebuke to the system of wholesale graduation and an endorsement of that which is in the line of true progress.

Organized in 1881, the Polyclinic was opened to practitioners in November, 1882. For the first year of its existence its class numbered 26, while for the first four
months of the session commencing October 1, 1883, more than one hundred practitioners have matriculated, a total of over two hundred and sixty within the first fifteen months of its existence.

We learn with pleasure that the management have purchased the property, a portion of which they have heretofore occupied, and that it is to be converted into a Polyclinic School and Hospital, thoroughly equipped with every requisite for post-graduate study.

THE SIMS MEMORIAL FUND.

In the present issue we commence the publication of the list of subscriptions to the Sims Memorial Fund. There is, as yet, hardly time to hear from many quarters, but a good start has certainly been made. Any amount, from one dollar upward, will be gratefully appreciated by the Committee. A small sum carries with it as good and as true a motive as does a large contribution. While the latter is always acceptable, the former will be warmly welcomed as affording opportunities for a more widespread expression of sentiment. We are glad to learn that many of the medical journals and medical societies are disposed to aid the Committee in making collections.

News of the Week.

PROFESSOR THEOPHILUS PARVIN, M.D., LL.D.—The Alumni Association of the Jefferson Medical College gave a reception in honor of Professor Theophilus Parvin, M.D., LL.D., on Monday evening, January 28, 1884, at the St. George Hotel, Philadelphia. A large number of representative medical gentlemen were present.

CONGRESS AND ADULTERATED FOODS.—The following resolutions were introduced last week by Mr. Green, of North Carolina, and referred to the Committee on Public Health:

Whereas, It is popularly charged and generally believed that divers and various articles of food, drink, and medicine are adulterated by admixtures with baser and usually deleterious substances; and

Whereas, Such adulterated compounds are injurious to public health, and calculated to shorten human life; therefore,

Be it resolved, That the Committee on Public Health be authorized and directed to inquire into the truth of said alleged abuse, and to report to this House the result of their investigation, at as early a day as practicable; and if it shall be shown that such practices exist, then to suggest or recommend in their report what further legislation, if any, is necessary to correct the wrong. And that they may the more effectually do their work,

Be it further resolved, That said Committee be, and they are hereby, empowered to send for persons and papers, and to employ such chemical and medical experts as they may deem necessary to carry out the end, aim, and object in view.

"ANNALES OF ANATOMY AND SURGERY."—The following announcement is made: "On account of the departure of the senior editor, Dr. Filcher, for Europe, in January, and the expected departure of his colleague, Dr. Fowler, for a similar trip abroad later in the season, the publication of the Annals of Anatomy and Surgery is necessarily suspended during their absence. If circumstances shall seem to warrant the resumption of the journal with the beginning of another year, due notice will be given."

THE NORTHWESTERN MEDICAL COLLEGE OF ST. JOSEPH, MO.—The State Board of Health of Missouri has fully exonerated the Northwestern Medical College, of St. Joseph, from all charges against it, and recognizes it as standing on a level with the best schools of the State. There was a full meeting of the Board, assisted by Drs. Rauch and Taliafara, of the Illinois Board.

THE KANSAS CITY HOSPITAL COLLEGE is the title of a new medical institution started at Kansas City, Mo. It contains an obliging mixture of allopathic and homoeopathic professors.

TUBERCLE BACILLUS NOTES.—Kusner has found that by injecting tuberculous sputa into the tracheas of dogs and rabbits, tuberculosis was produced; the injection of non-tuberculous sputa does not do this.

Weichselbaum, of Vienna, has published a criticism of Spina's work and a defence of Koch's conclusions.

Dr. Koch publishes, in the Deutsche Medicinische Wochenschrift, an elaborate review of the criticisms made upon the bacillus of tuberculosis and defends his original views as to its nature, retracting nothing. He brings forward no new experimental evidence. The prophylactic importance of the discovery is enlarged upon.

PROFESSOR GEGENBAUR, of Heidelberg, is likely to succeed to the Chair of Anatomy in the Berlin University, left vacant by the death of Reichert.

DIPHTHERIA AND THE MERCURIAL PREPARATIONS.—The number of persons who are using calomel or corrosive sublimate in the treatment of diphtheria seems to be increasing. Dr. Von Koszutski, in the Allgemeine Medicinische Central-Zeitung, has recently collected some of the reports upon this subject and contributed some results of his own experience.

A BRITISH TRIBUTE TO DR. MARION SIMS.—In commenting on the great professional services of Dr. Sims, the British Medical Journal says: "His achievements are written in imperishable letters in the annals of modern surgical practice; and there are thousands now living, and succeeding thousands in generations yet unborn will have reason to rise up and call him 'blessed.' The greatest success which any surgeon of genius can hope to achieve is to be able to definitely and largely add to the power of surgery to save life, to relieve misery, and to effect cure. This success Marion Sims attained in a degree which few can hope to attain."

THE PREVALENCE AND PREVENTION OF SYphilIS.—At a meeting of the Montreal Board of Health last December the following resolution was presented by Judge Dugas and unanimously adopted: "That in order to obtain a better knowledge of the sanitary state of the city a circular be addressed to all the physicians of Montreal and surrounding municipalities, requesting them to make known to this Board the result of their experience concerning the extent of the ravages of syphilis and of venereal diseases in general; to state whether they consider it opportune to establish restrictive measures for the prevention of those diseases, and what, in their opinion,
THE MEDICAL RECORD.

February 2, 1884.

would be the best means to be adopted for that end." The Canada Medical and Surgical Journal states that about thirty replies have been sent in, the general tenor of which is that the disease is very prevalent, and that restrictive measures are necessary.

BARNUM'S WHITE ELEPHANT seems likely to prove an object of pathological interest. The animal is said not to be white, or even gray, but to be of the ordinary color interspersed with pink patches. Professor Flower considers these patches to be due simply to a loss of pigment, while Mr. B. Squire contends that they are a form of skin-disease.

LEGISLATION AT WASHINGTON.—Mr. John J. O'Neill has introduced in the House of Representatives a bill to prevent the adulteration of food and drugs. It has been referred to the Committee on Agriculture, and is known as House Bill No. 899. It is apparently the same as the bill that was reported favorably by Mr. Orr, of the Committee on Commerce, winter before last. The Sanitary Engineer commends it.

THE COLUMBIA VETERINARY MEDICAL COLLEGE and the American Veterinary Medical College have united, and New York has now but one veterinary school.

A STATE WHERE THERE IS ROOM FOR MORE DOCTORS.—In Louisiana there is but one physician to every nine hundred and nine inhabitants, and the Medical Brief states that there are a number of places where physicians are actually in demand. Grand Cave, San Patrice, Robeline, Provencal, Prudhomme, and Pineville are given as places where openings exist. Although the ratio of physicians to population is large, it should be remembered that Louisiana is not a rich or thinly populated State.

"THE INTERNATIONAL REVIEW OF MEDICAL AND SURGICAL TECHNICS" is the title of a new quarterly journal published in Boston, and edited by Drs. Joseph H. Warren, Charles Everett Warren, and Willard Everett Smith. It is stated to be the official organ of the American Association of the Red Cross. The object of the editors is to collect and publish all the new medical and surgical inventions and devices as they appear.

NEW NAMES FOR FRENCH HOSPITALS.—There is at present a disposition, on the part of the Municipal Council of Paris, to effect a change in the names of the Paris hospitals. Many of the lycées have long since borne the names of persons connected with the Republic, and ceased to retain the names of their founders. A proposal has already been made to deal with the hospitals in a similar way, and to go so far as to suppress even such unpatriotic titles as "Pity" and "Charity," and to substitute for them "Solidarity" and the "Rights of Man." The "Hôtel Dieu" will henceforth be "Ambroise Paré;" "St. Louis" and "St. Antoine" are to bear the names of "Boerhaave" and "Velpeau" respectively. Its proposer, Dr. Flaux, is the author of "The Commune and the Civil War," and a member of the Municipal Council. The press are loud in their protests against this sweeping change of nomenclature, the Voltaire not excepted.

PROFESSOR BILLROTH'S ANTISEPTIC PRECAUTIONS.—The Vienna correspondent of the Gazzetta degli Ospitali was recently invited to a laparotomy in Professor Billroth's clinic, in the following note: "Dr. —— is here-by invited to the operation of ——, which is to take place ——. It is understood that Dr. —— undertakes not to visit the same day, before the operation, sick rooms, dissection rooms, or other places in the Pathological Institute, and not to wear clothes which he may be in the habit of wearing in visiting these places."

A GENERAL MEDICAL HOSPITAL FOR THE INSANE.—"A proposal is under consideration," says the Lancet, "in a philanthropic quarter for the establishment in London—with a branch establishment for convalescents on the Continent—of a general medical hospital for the insane and persons afflicted with what are supposed to be 'incurable' nervous diseases. The scheme is to place this projected institution on the footing of an ordinary hospital, with a staff of honorary physicians and surgeons who are not specialists, but who will be able to bring to the treatment of cases of mental derangement that general acquaintance with physiology, pathology, and therapy which—if it be true that mind is simply brain-function, and that mental disorder is only, and always, a symptom of physical disorder or organic disease—ought to be adequate for the investigation, and if possible the remedy, of mind-troubles. The institution will not be conducted as an asylum, but as a hospital; and, if necessary, application will be made to Parliament for special powers to carry it on without its being subjected to the interference of the Commissioners in Lunacy, although it will, of course, be at all times, and to the fullest extent, open to their inspection and amenable to their authority, so far as the protection and comfort of the patients who may be certifiable are concerned."

The idea of putting insane asylums more upon the basis of ordinary hospitals has been advocated for some time in this country.

CONDEMNING A PENSION SURGEON.—The board appointed by the Commissioner of Pensions to investigate the charges of irregular practices made against Dr. Azel Ames, a member of the Boston Board of Medical Examiners of the Pension Office, has made a report to the Commissioner, in which they say that, after careful examination of the affidavit laid before them, it is their judgment that Dr. Ames is shown to have violated the instructions to examining surgeons, and have been guilty of conduct unbecoming a member of the board to which he was attached, and that he is, therefore, unfit for the duties of such a position.

A PROPOSED NATIONAL PHARMACOPOEIA.—In the House of Representatives, January 8, 1884, read twice, referred to the Committee on Ways and Means, and ordered to be printed, Mr. Randall introduced the following bill:

A bill to prepare and publish a national pharmacopoeia for the United States:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Secretary of the Treasury shall, as soon as practicable, detail two officers of the Marine Hospital Service, and the Secretary of War shall detail two officers of the medical staff of the Army, and the Secretary of the Navy shall detail two officers of the medical staff of the Navy, for the duty of compiling and preparing a pharmacopoeia, which shall be known as the "National Pharmacopoeia of the United States of America," and shall be held and accepted as the standard for
the purveying, compounding, and dispensing of drugs or medicinal agents, and shall be taken as authority in the Treasury Department on all questions arising under the tariff laws of the United States with regard to the nomenclature, description, and purity of drugs or remedial agents, and shall further be received in evidence in the United States courts. And the matters contained in the said pharmacopoeia shall be free for use by all authors and commentators for the benefit of the medical and pharmaceutical professions and of the community at large; and it shall not be lawful for any one to reprint and publish the said pharmacopoeia as a whole.

Sec. 2. That the medical officers detailed as above provided shall invite the American Medical Association and the American Pharmaceutical Association, at their next annual meetings, to form committees of not more than three members from each of the said associations, which committees, if so appointed, may co-operate with the above-named medical officers in the preparation of the said pharmacopoeia, forming a board which shall have power from time to time to add to its number as may in its judgment be necessary, and which shall elect a chairman and a secretary, and adopt such rules as it shall see fit for the expediting and perfecting of the said pharmacopoeia, which, when completed, shall be printed under the supervision of the said board; and an edition of not less than 5,000 copies shall be printed for use in the several Departments of the Government of the United States, and the copies may be furnished to private persons in accordance with the provisions of section 3,899 of the Revised Statutes.

Sec. 3. That for the purpose of defraying the necessary expenses of preparing the said pharmacopoeia the sum of $5,000 is hereby appropriated out of any moneys in the treasury, not otherwise appropriated, and the same shall be disbursed under regulations to be prescribed by the Secretary of the Treasury.

Sec. 4. That the said pharmacopoeia shall be revised once in ten years, upon the plan embodied in this act.

[The necessity for such a work does not appear. In any event the proposed publication cannot be made as reliable as the one already sanctioned by the pharmaceutical and medical professions. It is somewhat curious to notice the intention of Government to protect this venture. Altogether it appears to be a scheme that is essentially Philadelphian in origin, and consequently cosmopolitan in aim. The profession is evidently satisfied with what it has, and why complicate matters by advocating a change which cannot possibly be for the better. —Ed.]

THE SIMS MEMORIAL FUND.

To the Medical Profession and Others throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting testimonial than obituaries and eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations, and such as have had the direct advantage of his personal skill are among the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulsion to the study of gynecological surgery in America. It is believed that the medical profession everywhere, the vast number of women who have received relief from suffering directly to him, and those who realize the benefits he first made possible, will gladly unite thus to honor the man through whose original and inventive genius such blessings have been conferred upon humanity.

At the suggestion of many friends, therefore, the subjoined committee has been organized, and it is proposed that a suitable monument be erected to his memory in the city of New York.

To this end the active co-operation of the medical profession and the many other friends of Dr. Sims throughout the world is respectfully solicited. Contributions of one dollar and upward may be forwarded to the journal which has been constituted the treasury of this fund—THE MEDICAL RECORD, New York.

The author proposes, in this volume, to give such information as shall enable microscopists generally to make photo-micrographs, and he introduces as specimens of the art about forty pictures, which are also employed in illustrating the text. From the preface we learn that the work is intended for beginners, and as there are at present many who are anxious to begin, the title will attract much attention to the book.

Part I. is devoted to a description of the apparatus and processes and introduces a photograph of the various instruments as arranged for work. The heliostat of Keith, the only one mentioned, is strongly recommended, and particularly as having been first made under the direction of Surgeon J. J. Woodward. While it is true that Mr. Kübel made this instrument at the suggestion of Dr. Woodward, it is also true that the doctor found it entirely inadequate for purposes of photo-micrography and discarded it. It is at best a flimsy toy, of no practical use. Of that bâte noir of the beginner, the adjustment of the beam, and not a trace of the instructions on arrangement of the light and focusing will be found meagre. Much depends upon the relative position of the primary and secondary condensers to the objective, and the absolute precision with which the light is centralized. The chapter on photographing proper are clearly written and will prove valuable to the inexperienced, not encumbered with the antediluvian formulæ.

The second part of the volume consists of plates with a pretty liberal descriptive text. These plates are reproductions by the "heliotype" process of negatives made from time to time by the author, the subjects being mostly histological. An attempt is here made to give the work a popular character, with the title "Elementary Lessons in Biology," and the subjects are selected in illustration of the fact that the lower forms of life are unicellular, while the tissues of the higher animals and plants are derived from cells. The list includes the algae, fungi, epithelia, blood-disks, plant structures—pollen-grains, epidermis, and hairs—diatoms, parasites, etc. If the young photo-micrographer is not more successful with his negatives than the author seems to have been he will have no cause to be particularly pleased with his work. The illustrations of vegetable tissues, when the structures present strong contrasts and the amplification is small, would be considered pretty successful for a beginner. In pathology—where the art is destined to be of great value—the only specimen we find is one fortunately labelled "round-celled sarcoma." We say "fortunately," for in truth the label affords the only clue to a diagnosis. The pictures of blood-disks are much better than those of many other subjects, but the only photo-micrograph that deserves a place in a work of the character and pretensions of the volume in hand is the one facing p. 190—a pustule of navicula hyra, magnified eight hundred diameters.

We are sure that the student seeking information upon the art of photo-micrography will not become discouraged from attempting the work from a perusal of this book. But our author seeks to disarm criticism by disclaiming any effort to equal the work of Dr. Woodward—work which is invaluable and will be enduring. Dr. Sternberg will find that the American microscopist will not be satisfied in starting out with the avowed purpose of attaining only a moderate success. We are only sorry to add that, in our opinion, the only encouragement the work will afford will be that which may stimulate some man to write a book on "Photo-micrographs and How to Make Them."

The author of the present unpretentious little work has already published a similar volume on Davos Platz, which is doubtless familiar to all interested in obtaining reliable information concerning foreign health resorts for phthisical patients. Wiesen is but little known at present, and being in consequence little visited, suffers more of the drawbacks of overcrowding. Those seeking information concerning new health resorts for consumption should read this guide-book.

This familiar visiting list comes to hand with its various tables thoroughly revised. It is well bound and of convenient size.

The views expressed in this little work are unique and interesting. Almost every page bears evidence of the author's wide acquaintance with the literature of his subject. The book is divided into two chapters. The first is given up to the discussion of the usual theories concerning the cause of phthisis. Dr. Parkin entirely rejects the "germ theory," and regards the presence of bacilli in tubercle as the effect, never the cause, of the disease. Phthisis, he maintains, is a general disease, inflammatory in nature, and produced by an external agent. This agent is malaria, and malaria is the cause of phthisis.

In the second chapter the "antidotal treatment" of phthisis is explained. According to the doctor, the proper remedy is carbonic acid gas, or those hydrocarbons which are readily converted into that gas when taken into the body. Carbonic acid gas is effective against phthisis, because it is the antidote to malaria, this poison being the cause of the pulmonary disease.

The volume is written in large, clear type, and is altogether very neatly gotten up.

The text of this work consists of five chapters, the first four being descriptive of the physical condition of the insane, the last being devoted to the subject of the commitment of the insane and the lunacy laws in various States. The first chapter describes the general appearance of the insane, physiognomy, posture, conformation of head, etc. The author omits some of the well ascertained facts on this subject, though he commits no positive errors. The second chapter is devoted to the condition of the special organs, the third to that of the bodily functions, the fourth to the examination of the patient, his dress, habits, etc.

Perhaps the author is not to blame that we feel a little disappointed after reading the book. For it seems to us when we have finished it that there is not a great deal to be learned through a physical examination of the insane. We are inclined to think that Dr. Hamilton has not made quite so much of his subject as he might, and that it should have been treated with more thoroughness and especially on the basis of a better classification than
the absurd one here adopted and prevalent among American asylum superintendents. For this we must add that the book is written in an easy and attractive style, and that it will interest the general reader. The ten lithographic plates accompanying the text are beautifully illustrated, and lithography, but we have seen better types than several of those which are presented.

The larger part of this book is essentially a directory to the various hospitals, dispensaries, asylums, homes, etc., in England, and a very useful book in the country, it is not of much interest to Americans. The second part consists of one hundred and sixty pages devoted to "Hints in Sickness," "Treatment of Emergencies," and "Sick room Cookery." It has no especial merit. The last section is frankly given up to advertisements of foods, medical preparations, mineral waters, and appliances. The book will doubt supply a want that is felt in England, and be of some value for reference in this country.

THE TREATMENT OF WOUNDS AS BASED ON EVOLUTIONARY LAWS. By C. Pfitzfeldt Mitchell, Member of the Royal College of Surgeons, etc. 8vo, pp. 29. New York: J. H. Vail & Co. 1883.

The argument submitted by the author of this little work was originally intended for contribution to medical literature, yet, from the general and widespread interest taken by the profession in the subject which it presents, we are pleased to see it published in this form. The subject is thoroughly handled in the minutest detail, the discussion presented in the most able manner, and will, we hope, command the earnest attention of the profession.

This is one of the most instructive little works that we have met in a long time. The author is a physician and pharmacist as well as a chemist, consequently the book is unqualifiedly practical, telling the physician just what he ought to know of the applications of chemistry in medicine. Dr. Ralfe is thoroughly acquainted with the latest developments of his science, and it is quite refreshing to find the subject dealt with so clearly and simply, yet in such evident harmony with the modern scientific methods and spirit.

This volume carries the work from p. 665 to p. 984. It is an especially valuable one, as it takes up the alkaloids of opium. All the articles are written with the thoroughness characteristic of the whole of this invaluable work.

The claim of Atfield's popular chemistry for the patronage of physicians and students is based on the fact that the author excludes all matter relating to compounds, which only interest the scientific chemist; that he includes a description of the chemistry of all remedial agents; and finally, that the paragraphs are so cast that the volume may be used as a guide in studying chemical experimentation. Then, of course, the modern chemical nomenclature; he has dropped the use of the words potassa, soda, etc., and uses potassium, sodium, etc., instead. The metric system of weights and measures ("that which," says Dr. Atfield, "is destined to supersede all others") is used.

We believe that Atfield's chemistry, in its present form, has its own against the numerous rivals which are now appearing. It is probably as good a manual as can be made on the plan adopted. The plan will, however, in time be abandoned, we trust. It is at best but a make-shift to teach a man enough of chemistry to enable him to remember a little chemical physiology. Chemistry ought to be taught as a preliminary study, and taught thoroughly, without any pharmaceutical bias. Then the matriculated medical student can study clinical chemistry with interest, intelligence, and profit.

This annual review contains the usual amount of bibliographical notices and abstracts. Too much space is occupied with the physiology of the sensory organs.

THE PHYSIOLOGICAL FACTOR IN DIAGNOSIS. A Work for Young Practitioners. By J. MILNER FOTHERGILL, M.D., Physician to the City of London Hospital for Diseases of the Chest, etc. New York: W. Wood & Co. 1883.

Dr. Fothergill's latest work is a thoroughly characteristic production of that prolific writer. It is intended to guide the young doctor about to begin his practice. Among much that is of great practical utility in this connection we still find the evidence of hasty composition. The author is not always accurate in his scientific statements, and his work is, for this reason, not strictly reliable. However, as the volume before us is intended for those whose recent scientific acquirements will readily enable them to detect faults, no great harm will result from the author's method of rather loose statements. As regards the unscientific portion of the book, it consists of comments, suggestions, and advice that will, if taken to heart, certainly better qualify the doctor to treat patients than much that has been written in a strictly scientific way. The "Physiological Factor" is not always made very prominent, and indeed the volume had better been called "Hints in Beginning Practice."

As the fourth English edition, from which the work before us is an American reprint, is separated from its predecessor by an interval of eleven years, ample time has elapsed for the production of new matter and for change of old opinions and methods of procedure; and that such has been pre-eminently the case with gynaecology no one acquainted with the history of medicine will undertake to deny. Of all of these advances and alterations Dr. Hewitt has taken due cognizance, so that the present edition is almost a new work. Much has been added and much rewritten, and seventy-nine new illustrations have been inserted. As the whole is characterized by the clearness, moderation, and thorough acquaintance with his subject which mark all of the writer's productions, the result deserves to be long continued.
MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, January 28, 1884.

S. O. Vander Poel, M.D., LL.D., President, in the Chair.

The Charge of Attempted Bribery.

The Comitia Minora, to whom was referred the charge of attempted bribery made by Dr. Isidor P. Oberndorfer at the annual meeting held October 22, 1883, reported that the charge had not been sustained by the evidence of the persons implicated in the accusation.

Unanimous consent was obtained, and the by-laws were suspended. The resignation of Drs. Samuel Sexton and John Hentley, as delegates to the Medical Society of the State of New York, were then read, and the Society elected, to fill the vacancies, Drs. W. Gill Wylie and Alfred L. Loonis.

Dr. F. R. Sturgis then introduced the following resolutions:

Resolved, That the Medical Society of the County of New York is heartily in favor of and endorses the formation of a State Board of Examiners, before which all future candidates for the practice of medicine and surgery in this State must appear for examination, as embodied in the bill prepared by the Committee on Legislation of the Medical Society of the State of New York, and that it urge upon the Legislature the necessity for the speedy enactment of such a bill.

Resolved, That a copy of this resolution, bearing the signatures of the President and Secretary of this Society, be sent to each member of the Legislature from this county, and to the Chairman of the Committee on Public Health in the Assembly, and of the Committee on Miscellaneous Corporations in the Senate.

This gave rise to considerable discussion, and the following substitute was offered by Dr. Roosa, and unanimously adopted by the Society:

Resolved, That the Medical Society of the County of New York is in favor of the passage of a bill to establish a State Board of Examiners, who shall determine the qualifications for a license to practise medicine in this State, to have the following resolution transmitted to the Legislature of the State, signed by the President and the Secretary.

Dr. Charles Heitzman then addressed the Society on the latest researches in embryology.

The following is an abstract of his remarks:

He first alluded to a recently published criticism of his book by S. Stricker, of Vienna, in which this most competent observer says that his doctrine so answers to the progress of histology that Stricker expects in the next ten years that it will be better than the older doctrine of the cellular state. In embryology the cell-doctrine, too, was rather an obstacle to a thorough understanding of the formation of the animal body.

The speaker next referred to the generally adopted ideas since Remak's times, according to which epithelial formations would be only the offspring of the two embryonal layers, the epiblast and hypoblast; whereas the development of the Wolfian bodies, and the aspiration of a portion of many others, the mesoblast, the former of connective tissue and muscle, should be an offspring of either the epiblast or the hypoblast, or both, were contradictory to the exclusiveness of epithelial layers. The ovum as well as the spermatoids are strictly epithelial formations, and nevertheless the whole organism is formed out of them. The idea of His, of an immigation of connective tissue elements into the ovum, is thoroughly hypothetical.

Dr. Heitzman referred to the discoveries of O. Hertwig and Pol, according to which the sauce of the germinal vesicle takes active part in the segmentation, and the spermatoid, being a nucleus-like formation, fuses together with the blasodeum nucleus, the segmentation was best studied by Coste, Oellacher, and Kolliker on the ovum of the chick; but an important fact was overlooked by all observers, viz., that the segmentation does not mean separation of the globules into so-called cells, for the great majority of them remain connected not only by an intervening cement-substance, but by delicate spokess of living matter, traversing the cement substance. Even after segmentation is far advanced, the majority of the newly formed elements remain interconnected, thus establishing the continuity of a tissue, in the sense of the new theory. A comparatively small number of segmentation-globules become separated from the main bulk of the germ, being enabled to change form and place; their ultimate fate, however, is not known.

In the fructified, unhatched ovum of the chick, as a rule, only two layers are discernible, the upper being of an epithelial nature, the epiblast, the lower being generally termed hypoblast. Many excellent observers claim that the mesoblast is an offspring of the epiblast. The recent researches of Köpf and Benecke, of Königsberg, and of Karl Koller, of Vienna, the latter's more particularly, on the chicken-egg, have made it clear that the primitive trace, or primitive ridge, considered as the essential part of the mesoblast, originates excentrically at the boundary line, between the area pellucida and area opaca, in the shape of a sickle, whose anterior point grows into the area pellucida in a meridional direction, being closely attached to the epiblast in the region of the sickle-furrow and the primitive furrow.

The reader's researches go to prove that the view of Götte, Disse, and Rauber are correct, according to which the sub-epithelial layer furnishes the mesoblast, and from this is separated, at the bottom of the blastoderm, a single layer of flat epithelia, the hypoblast-proper. The original layer is not a mere aggregation of so-called cells, but a true myxomatous tissue, with light fields of basis-substance, in which the living matter, in the shape of a reticulum, remains discernible. The primitive trace,
though starting from the area opaca, the germinal dam of the authors, is, to a great measure, a formation of the lower layer of the blastoderm, which, from the condition of a myxomatous tissue, returns into the stage of embryonal tissue.

The epiblast unquestionably participates in the formation of the mesoblast, and so does, in all probability, also the hypoblast. But neither in the former nor in the latter is there at any time a separation into isolated elements.

The methods hitherto applied for embryological research were mainly the treatment with osmic and chromic acid solutions, with subsequent clearing in oil of cloves and mounting in Canada balsam. Specimens thus obtained never show the minute structure of the first-formed tissues. The reader adopted a method far more recommendable, viz., hardening in chromic acid solution, beginning with a 0.1 per cent. and advancing toward a 0.5 per cent. concentration. Imbedding should be done only in a solution of celluloidine in alcohol and ether, which saturates the delicate tissues and holds them together. Both the hardened celluloidine and the germ are cut simultaneously with a razor, or, preferably, with a section-cutter. The sections should be mounted in no other liquid but dilute glycerine.

In his discourse referred to the advantages afforded by the celluloidine in the study of the delicate structures of the brain.

Dr. A. Jacobi asked Dr. Heitzman why he called the bodies outlined upon the blackboard elements and not cells?

Dr. CORNING referred to what the study of embryology had done for the knowledge possessed to-day concerning the anatomy of the brain.

Dr. Heitzman closed the discussion with a brief account of his views concerning the formation of what are called cells and the basis-substance, which have already been laid before the readers of THE RECORD.

The President announced the death of Dr. J. Wilhelm Frankl and Dr. James Mooreshead. He then introduced Dr. W. GILL Wylie, who read a

MEMOIR OF THE LATE J. MARION SIMS, M.D., LL.D.,

in which he gave a sketch of his early history, his struggles at the beginning of his professional life, a graphic outline of his first experience in treating vesico-vaginal fistula, and a résumé of the obstacles which were encountered and overcome in establishing the Woman's Hospital, taken entirely from autobiographical notes which will soon be published. The memoir closed with a touching reference to the simplicity, frankness, and the peculiar traits in Dr. Sims' character, as revealed to one who was most intimately associated with him for several years in private and hospital work.

The Society extended to Dr. Wylie a vote of thanks for his interesting memoir.

THE CAUSATION OF CROUPOUS PNEUMONIA.

Dr. A. Jacobi, Chairman of the Committee on Hygiene, read a communication which he had received from Dr. Seibert, of New York, in which the proposition was made to issue circulars, to be endorsed by the Committee on Hygiene, and to be sent throughout the country asking physicians to report with reference to the causation of croupous pneumonia, the expense to be defrayed by Dr. Seibert.

On motion, the Committee on Hygiene was authorized to issue such circulars.

The President said he was pleased to have Dr. Jacobi's endorsement of this plan of work, as he had recommended in his inaugural address that work of a similar kind be done among the members of the Society, and a committee had since been appointed to perfect plans by which it could be best carried on.

The Society then adjourned.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE DIRECT TREATMENT OF SPINAL CARIES.—PROFESSOR STOKES ON NERVE-STRETCHING—ROYAL COLLEGE OF SURGEONS—ACTINOMYCOSIS.

LONDON, January 19, 1864.

A very interesting paper was read by Mr. Frederick Treves at the last meeting of the Medico-Chirurgical Society (January 8th), on the direct treatment of spinal caries by operation. Mr. Treves remarked that the gravity of spinal caries is largely due to the depth and inaccessibility of the diseased area. The diseased bone cannot be removed and the morbid products have to travel a long distance to be evacuated. Immense purulent collections are thus induced, and these are usually opened at a point remote from the original seat of the disease. Mr. Treves proposes to reach the anterior surfaces of the bodies of the lumbar (and, with some reservation, last dorsal) vertebrae from the loin. A vertical incision is to be made close to the outer edge of the erector spine, the soft parts of that muscle and the quadratus lumbarum divided, the psosas muscle divided, and the vertebrae reached by continuing the operation along the deep aspect of that muscle. Mr. Treves claims that by this operation the vertebrae can be examined, diseased bone removed, and a ready exit given to all morbid products, a psosas or lumbar abscess opened while yet small and before a large abscess cavity has formed, while a large abscess exist it can be evacuated at its point of origin and at a spot corresponding, in the recumbent posture, to its most dependent part. Mr. Treves has performed the operation in three cases, all of whom made a good recovery. The paper led to a very interesting discussion, in which many of the leading surgeons present took part.

Mr. Bryant congratulated Mr. Treves on his application of general surgical principles to spinal disease, but remarked that the operation was only likely to be successful for the removal of bone in a limited number of cases. Many abscesses originated independently of spine, and led to suppuration of the spine, most of which ran their course without suppuration.

Mr. R. W. Parker thought the operation would be valuable for the letting out of pus, but as regards the caries, it would be better not to interfere.

Mr. Savory considered that by no reasonable operation in this region could the parts be sufficiently exposed to be examined and treated.

Mr. Eve brought specimens showing that in nearly all cases the twelfth dorsal vertebra was affected, and as this could be reached by the proposed operation, these specimens at least supported Mr. Treves' practice.

In reply, Mr. Treves said that he was opposed to the indiscriminate removal of diseased bone. The main object of his operation was to retain an operation, by which the lumbar vertebra could be reached and pus arising from bone disease be evacuated at its point of origin. Mr.
Bryant's remark that pus in contact with bone might cause erosion of the bone was a strong argument for opening a psoas abscess as soon as possible.

I recently forwarded you a brief account of Professor Marshall's suggestions concerning the role of nerve energy in locomotor ataxy, in which the sciatic nerve was stretched. In both cases considerable relief from pain followed the operation, although in one case severe pain at the site of the operation, with spasmodic contraction of the muscles of the legs, persisted for some hours. Professor Marshall considers a force of ten pounds sufficient for the sciatic nerve, and proposes to employ a dynamometer in future operations to estimate the force exerted.

At the quarterly meeting of the Council of the College of Surgeons of England, the second report of the committee on the mode of election to the Council and on other matters was presented and adopted. It is now proposed to allow voting by means of voting papers at the elections of councillors, thus taking the first step toward the removal of an old grievance which has been a bone of contention for years. As the matter has hitherto stood, country Fellows, residing at considerable distances from London, have practically been deprived of the power of voting by the rule requiring them to attend and vote in person.

Mr. F. Treves has at present under his care at the London Hospital, and exhibited at the Pathological Society, on January 4th, a case of actinomycosis which had been sent up to be under his care by Mr. W. K. Treves, of Margate. Poufick has described the disease in cows and horses, but no case has yet been reported in man, and Mr. Treves' patient was a man forty-six years of age. The disease began as a nodule on the left side of the neck and had spread downward over the left side of the chest. All stages of the disease were present, from minute solid growths to large suppurating and sloughing masses.

CONCERNING THE ADVICE GRATIS SYSTEM.

To the Editor of The Medical Record.

SIR: So much discussion has been carried on of late in relation to the question of out-door medical relief, and the discouragement given by many lecturers in this connection, so much occurring in mankin; that I think it well to trespass upon your time in order to lay before you the practical difficulties in the way of reform in this matter.

The question must be regarded: 1st, from the standpoint of philanthropy and political economy; 2d, from the standpoint of the poor; 3d, from a professional standpoint.

From the first point of view sickness must be regarded as a necessary evil, but one which hinders or destroys the usefulness of the individual to the community, and in the case of contagious or infectious disease is dangerous to others than the patient. The community has therefore a right to interfere to prevent or heal sickness. It has, in the case of death or disablement, sickness tends to increase directly the amount of pauperism, and hence of crime. Therefore it is the duty of the community to reduce the amount of sickness and shorten its duration as best it may. For these reasons free dispensaries are necessary, and to a certain extent fulfill their objects. It is not, however, the right of a citizen who has means to obtain free medical relief. It is as dangerous, and tends as much to produce paupers, to give free medical advice to all comers as to give grocers. Therefore, as the present system does, to a certain extent, just this thing, the present system is wrong to just the extent in which it gives to those who can pay for advice. There is, however, one point not generally considered: The sickness of the supporter of a family in many cases cuts off entirely and immediately the income of the family. Is it better that the savings of such a man should be devoted to payment for medical attendance, or should remain to pay for the expenses of the family until the laborer be restored to health? I speak of people with small incomes, say one dollar and a half to two dollars a day. Is one more likely to pauperize by treating patients free and letting them pay for their own necessities, or by making them pay for treatment and letting some one else give them their food and lodging? Any one familiar with the condition of many respectable families in New York will see at once how grave this question is.

The poor seem to regard the question as follows: Some seem to think that while they are well they can take care of themselves, but when ill, the wealthy must care for them; that they are not bound to make any provision against the time of sickness. Others again have so small an income that such provision is impossible. Still others naturally ask, why should we pay for what is held out to us on all sides free? Some think that while they can pay a small fee, the advice obtained for their money is worthless, and that they can get good advice at the dispensaries free. With these it is a question of good advice for nothing or poor advice for money. Finally, there are some who would rather die than seek relief in the forms now held out to them as the profession regards them from various sides.

The clinical teacher wishes material for his lectures and must get it as best he may. He might say that no one can deny the utility of clinical instruction; that the subdivision of material caused by the large number of free dispensaries compels him to take such patients as he can get, without inquiring too closely into their circumstances; that it is not an issue which would be impossible. Some teachers may add with truth that they try to prevent people with means from receiving treatment at their clinics.

Physicians who are striving by hard work to earn a living from their practice complain that they are ruined by the system that every free dispensary takes cases from those of their patients; that in the face of the sharp competition with men who receive pay for their services, they must also compete with institutions which indiscriminately give advice and medicine free.

The dispensary physician does his work in the main for two reasons: the experience, and a certain prominence given to him by being connected with a dispensary for his labors. I speak as such a physician. I do not think that a dispensary physician desires to increase his classes at the expense of neighboring medical men; nevertheless dispensaries do take paying cases from such men. This shows beyond doubt that patients unfit for free treatment receive it. This is an evil much more serious to the community than to the profession, and what shall be the remedy? We cannot close all dispensaries because their privileges are abused by a certain class of patients. We cannot refuse aid to the deserving for fear the undeserving should profit by our generosity. It is difficult to see how the problem can be solved. Feeble efforts are made in certain institutions to do something with the needy; but nothing is possible by making a small charge for advice. This is said to help the patients to retain their self-respect. Self-respect at one dollar a month is certainly cheap. This system, moreover, is bad because it discourages the very poor, those most deserving of medical charity, from applying, while it encourages people of fair means, those who should and can pay aU a moderate fee to a physician, to seek relief at public institutions. Inquiry into the condition of each applicant, while it would do much to diminish the evils complained of, is practically impossible. Even a comparatively small dispensary would require a large staff of trained, efficient, and honest visitors, who would be difficult to procure. Besides, where are we to draw the line between patients who can and cannot pay? The "provident" or "nu-
tual assurance" system, which works well in some parts of England, would be difficult of application here, owing to the very different social conditions which obtain. We cannot trust the poor to the private charity of individual physicians, I fear. Were the profession recruited from the ranks of angels, such a system might work. True, there is no class of men who do more quiet and unobtrusive charity than physicians, but for such work some form of organization is necessary. The suggestion made by one of your correspondents, that physicians who are injured by the present system should co-operate to do their own charity, hardly seems more than trying to diminish the evil to a certain number of medical men, by giving to themselves some advantages now held by others, and increasing still further the number of means whereby free relief may be obtained.

I have tried to look at the question fairly in all its bearings. I see no practical solution of it in New York at least. Perhaps some of your readers may be able to suggest some plan whereby the evils of the system may be reduced to a minimum and its efficiency continued. Of course, the first step toward its solution would be made much easier should all of the dispensaries act in concert. Any effort made by a single dispensary would probably be a failure. It seems to me that we do not want a reduction in the number of dispensaries, for the city is large and it is well to have many centres for relief distributed throughout its extent. We need some practical means of sifting the undeserving from the deserving applicants for relief. Can any one suggest such a means?

J. West Roosevelt, M. D.,
Attending Physician Roosevelt Hospital, Out-Patient Department.
36 West Eighteenth Street,
January 18, 1884.

THE SECOND EXAMINATION IN THE ARMY MEDICAL CORPS.

To the Editor of the Medical Record.

Sir: It has been brought to my notice that serious misapprehension exists as to the character of the "second examination" in the Army Medical Corps, or the examination for promotion, as it is designated in Army Regulations. In view of the fact that an article by Assistant Surgeon R. W. Shufeldt, U.S.A., and published in your journal, has in a great degree caused this misconception, or has contributed to its extension, it has been thought best, with the approval of the Surgeon-General, to correct this, by giving in your columns an authentic and exact description of that examination as it is, and has been for the past twenty years conducted.

As the subscriber has been detailed as the presiding officer of every successive Examining Board for admission of candidates, and for promotion, since the death of Surgeon Tripler, in 1866, it cannot be questioned that he can speak from personal knowledge and experience. Every one of the present corps of assistant surgeons, and quite one-half of the surgeons-major, has been examined personally by him. No other member of the Medical Corps of the Army has had an experience which approaches this; except, perhaps, the late Surgeon Thomas G. Mower, U.S.A., of honored memory, in days long past. And as the subscriber was himself in those days examined by Surgeon Mower, he can speak also authoritatively as to the method then followed. He can assert, then, positively, that the general plan and scope of the first examination has not varied materially in over thirty years. There is but one set form for the information of candidates desiring to enter the Medical Corps of the Army, issued by the Hon. Secretary of War, and to be had by application to the Surgeon-General's office, or to the President of the Army Medical Examining Board now in session in this city.

The second examination, or examination for promotion, has been made rather more rigid than formerly, by successive instructions from the Surgeon-General's office, at various times during this same period—the late Surgeon-General Thomas Lawson, U.S.A., taking the first decided steps in this direction. A few other recommendations have been made from time to time, by different boards over which the subscriber has presided, at various intervals during this past period.

It was thought, until the publication of the article by Assistant Surgeon Shufeldt, that the general plan now followed in this examination was fully understood by the corps; but it seems from it that there is a misunderstanding, and that Dr. Shufeldt has, unintentionally, I doubt not, conveyed a wrong idea of the subjects embraced in that rule, without stating the reasons why, in some special cases, subjects gone over in the first examination are sometimes introduced in the second, but never without having apprised the candidate that such would be the case. Briefly, then, as I do not want to trespass on your valuable space, the second examination is designed to test the fitness of the officer for promotion, by demonstrating whether he has kept pace with the progress of medical science during the five or more years he has been in service. An abstract of the record of service of the officer ordered for re-examination is in every case furnished the Board from the office of the Surgeon-General, and Professor Coues is perfectly correct in his statement that his standing is thoroughly understood by the Board before the examination. The second examination is generally commenced by the president, who runs over the abstract of the officer's record of service, and inquires of him if he has regularly received his medical journals from the Surgeon-General's office, and if he has had opportunity to read them. He is asked if he has had any interesting or important surgical cases in the field or elsewhere; the details of operation, treatment, progress, results, etc., of some one or more of which he is requested to describe, and is questioned upon—scarcely ever in a set form of questions and answers, but as a simple professional conversation. He is asked to specify and describe any new operations, instruments, remedies, modes of treatment which have been introduced since his first examination, and his experience therein, if he has had any. He is asked a few questions as to surgical anatomy—a very few pertinent questions on these subjects will suffice to show the Board whether he has kept up these studies, and if he answers them satisfactorily the subject is not pursued. It is only from a manifest failure to do this, that this rule is departed from, or the examination prolonged. He is requested to relate some of his cases of obstetric practice, and disease of women and children. He is questioned more fully on matters of practical hygiene, his action in case of epidemics or infectious diseases approaching or present; his method of dealing with emergencies, and the sanitary recommendations he would, in certain specified cases, feel it his duty to make. And this is all.

In ordinary cases the subjects called "literary and scientific"—including physics and chemistry, which are in the first examination preliminary to the professional examination—are not touched at all in the second examination. In a few special cases it has been found that a candidate, while passing a most creditable examination upon all professional branches, has failed to reach the required standard in physics or chemistry; under such circumstances the candidate has been recommended qualified for appointment as assistant surgeon, but admonished that at his second examination—for promotion—he must make good these deficiencies, thus making his passage at this examination more probable. The second examination is upon which he is to be re-examined are clearly specified.

As to the "Treatment of Science by the Military Method," your correspondent, Dr. Godfrey, of New Orleans, has most satisfactorily and effectually disposed of Professor Coues' strictures. A taste for natural science, or proficiency in some special branch thereof, is unques-
tionably a very desirable accomplishment for a medical officer, who may, under certain circumstances, have special opportunities for the pursuit of this study; but it cannot be denied that it may be indulged in to the exclusion of the legitimate and essential requirements of his professional position. An army surgeon must "know a commanding officer," must "attend sick-call," and "see patients." If he becomes convinced that he is doing these duties in a "perfunctory way," he certainly should have the conscience to resign his commission, as Professor Coues, who so truly the "forbearance" of the Board, made haste to do. It requires much "audacious candor" to acknowledge that one in the Medical Corps of the Army "has never heard of" Laennec and his little theory, or does not know that persons suffering from glaucoma might be saved from total blindness by iridectomy! It did not require his "cheery reply" as to the "aspirator" to satisfy the Board that Dr. Coues was a proper person to recommend for promotion; but the "audacious candor" of his confessions since has taught the Board that their "forbearance" was mistaken, and they probably would not repeat the error of recommending him for promotion at once without requiring him to make up his deficiencies. Although he made that case for a man who had distinguished himself, therefore the Board simply advised him of his deficiencies and did not suspend him.

Assistant Surgeon Shufeldt very correctly states the facts up to a certain point, and there his imagination runs away with him. He says: "A young man is found qualified to enter the Medical Corps of the Army. As the preparation for this examination he is no doubt trying, the first impulse after becoming accustom to the novelty of freedom he at first experiences is to rest for a month or two, then follows a reading of the journals, so generously furnished by the Surgeon-General's office; then, a taking up again of his old textbooks as they commence to present themselves the rest of his fancy picture is compiled for. The "young man" has only to continue in the course above specified to become fully qualified to answer any questions that will be asked at his second examination without "special preparation." If he has been admonished to make good any deficiencies, these have been clearly specified, and he knows that no other "special preparation" is necessary, and if the young medical officer takes interest in his duties and reads the journals and textbooks so generously furnished, it is difficult to understand why there should be any "dread" of the second examination. Such can only be present in cases of conscious neglect. We have been told that certain persons under certain circumstances have no "good faith" to the law. Conscious neglect of daily opportunities can only render it necessary to "spend three or four months" before the second examination, "in cramming to prepare for it." "Naturally," the "unanimous verdict" in such cases will be that the system "is a bad one."

An extended inquiry among the members of the corps shows that there is little question as to the propriety and necessity of this second examination. Somebody or organization must have the duty of determining the fitness for promotion, and it is assigned by law to the Examining Board, which may, in some cases, have imposed the special condition that certain original deficiencies must be made good. The high standard attained by the Army and Navy Medical Corps is the best evidence of the excellence of this system. It certainly has not proved practically to be the "perfect break to professional progress and excellence" so pathetically pictured by Dr. Schufeldt. On the contrary, it is undeniable that the stimulus of looking forward to this second examination, for the first five years of service, has confirmed many a "young man" in his habitual study, who might otherwise have degenerated into a sutler's store lounging.

Joseph B. Brown,
Lieutenant-Colonel, Surgeon U. S. A.

Navy News.

Official List of Changes in the Medical Corps of the Navy, for the week ending January 26, 1884.

Anderson, F., Passed Assistant Surgeon. Granted leave of absence six months.

Flits, H. B., Assistant Surgeon. Detached from the Jamestown and ordered to the Coast Survey Steamer Gedney.

Whiting, Robert, Passed Assistant Surgeon. Detached from the Hospital, Norfolk, Va., and ordered to the Colorado.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, from October 1, 1883, to December 30, 1883.

Bailhache, P. H., Surgeon. Relieved from duty at Cape Charles Quarantine Station, October 13, 1883. Detained as member of Board to examine candidate for promotion, October 30, 1883. Granted leave of absence for thirty days, November 27, 1883.

Hutton, W. H. H., Surgeon. Granted leave of absence for twenty days, October 1, 1883.

Wyman, Walter, Surgeon. Detained as member of Board to examine candidate for promotion, October 30, 1883. To proceed to Norfolk, Va., to investigate the conduct of the Service at that port, December 31, 1883.

Long, W. H., Surgeon. Leave of absence extended ten days, October 26, 1883.

Murray, R. D., Surgeon. To proceed to Ship Island Quarantine Station, October 17, 1883. To inspect sites for quarantine stations, November 30, 1883. Granted leave of absence for twenty days, December 18, 1883.

Smith, Henry, Surgeon. Granted leave of absence for twenty-five days on account of sickness, October 13, 1883. Relieved from duty at Norfolk, Va., October 17, 1883. To report to Surgeon Swetille, at New York, for temporary duty, November 27, 1883. Relieved from temporary duty at New York, and placed on waiting orders, December 31, 1883.

Fisher, J. C., Passed Assistant Surgeon. When relieved by Assistant Surgeon Banks to proceed to New York for duty, October 29, 1883. Granted leave of absence for thirty days, November 28, 1883.

Goldsborough, C. B., Passed Assistant Surgeon. Granted leave of absence for thirty-two days on account of sickness, October 18, October 20, and November 1, 1883.

Irwin, Fairfax, Passed Assistant Surgeon. To proceed to Norfolk, Va., and assume charge of the Service, relieving Assistant Surgeon Glennan, October 16, 1883.

Mead, F. W., Passed Assistant Surgeon. To proceed to Portland, Oregon, inspect the Service, and report the condition of Assistant Surgeon Devan, December 5, 1883. To return to station, Port Townsend, Wash. Ter, December 18, 1883.

Cook, H. P., Passed Assistant Surgeon. To proceed to Charleston, S. C., for duty, November 27, 1883.

Banks, C. E., Assistant Surgeon. Detailed for temporary duty at Georgetown, D. C., October 11, 1883. Granted leave of absence for thirty days, October 12, 1883.

Peckham, C. T., Assistant Surgeon. To proceed to Wilmington, N. C., and assume charge of the Service, relieving Passed Assistant Surgeon Irwin, October 16, 1883.
DEVAN, S. C., Assistant Surgeon. Granted leave of absence for ninety-five days, on account of injury, and sickness resulting therefrom, November 15, December 5 and 22, 1883.

BEYAN, A. D., Assistant Surgeon. To proceed to Portland, Oregon, and assume charge of the Service, December 29, 1883.

GLENNAK, A. H., Assistant Surgeon. To proceed to New Orleans, La., for duty, October 17, 1883.

WASDIN, EUGENE, Assistant Surgeon. To proceed to Mobile, Ala., for temporary duty, October 11, 1883. To proceed to Galveston, Texas, for temporary duty, November 17, 1883.

BENSON, J. A., Passed Assistant Surgeon. Promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from October 1, 1883. October 4, 1883.

BANKS, C. E., Passed Assistant Surgeon. Promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from November 1, 1883. November 6, 1883.

**Convallaria Majalis.**—Dr. Squibb believes that the fluid extract of the root of this plant is the best preparation, and that it is a drug whose action as a heart tonic is somewhat different from that of digitalis. Dr. Squibb does not seem to be aware of the elaborate studies of Schmiedeberg and others upon this point.

**The Shroud.**—The undertakers have their trade journal too. It is called *The Shroud*, is in its third year, and appears prosperous. The end which it serves apparently justifies the means.

**A Grave Suggestion.**—The notice of an operation at a surgical clinic, in beautiful writing, carefully tucked upon the clapboards of an undertaker's office near a large metropolitan hospital, is an offset for an undertaker's sign which read: "All requisites for a first-class funeral furnished." "All the Year Round," Act I., Scene 1.

**The Antiquity of the Use of Convallaria Majalis as a Medicine.**—Dr. Edward Drummond, of Rome, writes to *The British Medical Journal* (see No. 1194, November 17, 1883, p. 970), that he has lately met with an account of the use of this drug in cardiac disease, as far back as the commencement of the seventeenth century, in an old Italian book of "Commentaries on the Materia Medica of Dioscorides," by Dr. Pietro Andrea Matthioli, published in Venice in 1621, and Dr. Drummond gives the following interesting translation:

"The Germans use lily of the valley to strengthen the heart, the brain, and the spiritual parts, and also give it in palpitation, vertigo, epilepsy, and apoplexy; also as a remedy for the bites and stings of poisonous animals, to quicken parturition, and for inflammations of the eyes. For this purpose they are wont to prepare the wine from the flowers at the time of the vintage, and then infuse it in old wine for forty days in the sun, and subsequently distil and re-distil (but not many times), along with lavender-flowers, rosemary, and other aromatics. They then preserve it as one of the most precious things to be found amongst medicines, and they call it 'aquae aqua' as 'a vessel of gold and silver.' The waters are again kept in reserve in case of sudden attacks. They even believe that given to persons actually in articulo mortis it is able to prolong life for several hours. In this, however, they are not unfrequently deceived, as I have myself witnessed."

**Hospital at Mobile, Ala.—** It appears that the faculty of the Mobile Medical College have control of this hospital. They have addressed a circular to the professors—just which goes, of course, to the people—in which they offer gratuitous treatment to a great number. Its first page details appropriate treatment of general and special diseases. This is, of course, in spirit, if not in act, a violation of the Code of Ethics, but as the same course is adopted by almost every medical college faculty, it is difficult to see how the abuse can be checked and the representatives of it held to a just and proper accountability to the profession. There can be no question as to the unavoidable results of such a course; firstly, what physicians, as organized bodies, are now culpably doing with perfect impunity will be soon done by individuals also; and secondly, as this great abuse of gratuitous services given to the public is more general and more diffused, so will paid service become less and less, and the profession be grievously injured.

In Philadelphia twenty per cent. of the professional work done is given without charge to the public, and so much money is withdrawn from the profession. It is a very great, growing, and dangerous evil. Medical societies must deal with it, and deal with it promptly and fully. — *Gailard's Medical Journal.*

**The Summary,** a journal of medical news published in Lansdowne, Pa., presents holiday attractions in its December number. Its first page details appropriate treatment for a case of "Bilious Pleurisy, or Pneumonia." Further on leucorrhoea is treated by a sponge-tenant inserted into the vagina. The author uses a "speculum which is like an old-fashioned candlestick," but "hopes to see a common-sense speculum in the near future." This is not all. The mechanism of the circulation of the blood is the topic of the closing words: "We are taught by Dunglison and others that the heart circulates the blood. I cannot conceive how the heart has any inherent power in itself to force twenty-five pounds of blood, more or less, through itself in the course of a few seconds, but I can comprehend how the blood may make its revolution through the heart and systems at the time specified by electric action, positive and negative, upon the principle of attraction and repulsion."

**The Relations in Which Medical Men Stand to the Law.**—Dr. Charles G. Garrison, in reporting to the Camden County Medical Society (*Medical Bulletin*), summarizes the relations of physicians to the law under these heads: "1. As a plaintiff: There is nothing in the profession peculiar to the physician. A 'visit' *œ per se* has no value in the courts; not the highest nor the lowest in the scale of demand. 'A professional visit, at the request of defendant,' is recommended as a proper form. The defense that he did not cure or benefit defendant is no bar to recovery, as skill and care, not cure or benefit, are the conditions of the implied contract. 2. As a defendant: The law presumes that a physician agrees to furnish the fair average skill in the art, and not the highest, and not the lowest, to the law. 3. As a witness: This may be ordinary or expert. The ordinary witness testifies only in regard to what he saw, heard, or observed in the case, the same as any other witness. As expert, the position of the physician is judicial, and he should be called by the court, and not by the contestants."
Original Lectures.

ON THE
METHODS OF STUDYING THE BRAIN.

The Cartwright Lectures, delivered before the Alumni Association of the College of Physicians and Surgeons, New York, February 2, 4, and 6, 1884.

By Burt G. Wilder, M.D.,
Professor of Physiology, Comparative Anatomy, and Zoology in Cornell University, and of Physiology in the Medical School of Maine.

Lecture I.

LIMITATION OF THE SUBJECT TO MACROSCOPIC ENCEPHALIC MORPHOLOGY—METHODS OF REGARDING THE BRAIN BASED UPON ITS CONDITION IN EMBRYOS AND IN AMPHIBIA.

Mr. President, Ladies, and Gentlemen: In fulfilling my acceptance of your invitation to deliver the lectures upon the Cartwright foundation this year, I desire to express my wish that such testamentary provisions may be multiplied, my pleasure in addressing an Alumni Association which includes so many of my former pupils, and the sense of mingled eagerness and hesitation with which I speak upon the brain in a city which has a Neurological Society and is the meeting-place of the National Association.

The facts and considerations to be laid before you are exclusively morphological: Comparative anatomy, general zoology, and embryology have place only, in so far as they elucidate human anatomy and histology, physiology, pathology, and psychology are omitted altogether.

These latter methods of regarding the brain, it is true, immediately preserve the ultimate purpose of the physician to recognize the nature and causes of encephalical disorder, to anticipate results, and to avert such as may be undesired; but surely it is equally true that microscopical, experimental, pathological, and psychological observations and discussions are more reliable and fruitful when based upon that living knowledge of the visible constitution of the organ concerned, which is to be gained only through prolonged personal and familiar acquaintance.

The title of these lectures should read as follows: Outlines and Illustrations of Some Methods of Regarding, Obtaining, Preserving, Examining, Figuring, and Describing the Brains of Certain Amphibia and Mammals, which have proved useful in the anatomical laboratory of Cornell University, which appear to be unfamiliar to many physicians, and which it is hoped may aid them in acquiring, retaining, and imparting clear, real, and accurate knowledge of the normal, macroscopic structure of the human brain.

The methods above indicated fall naturally into three categories, mental, manual, and verbal, involving, respectively, the recognition of ideas, the performance of manipulations, and the employment of terms. I shall first offer some general propositions which, in a somewhat extended experience, I have found to facilitate the comprehension of the brain as a whole. Then I shall describe certain ways and means of normal encephalotomy. At the closing lecture, in illustration of the results of these methods, I shall ask your attention to features of the brain which are not infrequently overlooked or misunderstood; and finally submit to you some considerations respecting the employment of certain terms of description and designation which are not in common use.

Consider a human brain. Various viewed, it consists of two, four, six, or more than one hundred parts visible to the unaided eye. A congeries of comparatively simple cells and fibres, yet in action how unlike ligament and connective tissue. Soft, yet moulding the skull upon itself. Confined within the head, yet well-nigh omnipotent throughout the body. At once the ruler and the servant of all the other organs. A mass of matter, yet ministering directly to mind. Who can fitly describe it? Who can hope to comprehend it? No wonder that so few truly wise and candid men pretend to really understand the brain.

Before suggesting the means by which the hopelessness of this task may be diminished, permit me to comment briefly upon some methods of regarding the brain which, so far as I can judge from standard text-books, and other sources of information, are not altogether unknown at the average English and American medical college:

1. The brain is regarded as a fibro-cellular mass, penetrated here and there by inconsiderable cavities.
2. Now that these cavities are no longer supposed to be the "reservoirs of animal spirits," or the "receptacles of the excrements which are separated in the nourishment of the organ," all use and significance seems to be denied them.
3. Little attention is paid to the membranes which line these cavities and invest the entire organ.
4. For lack of a clear recognition of the nature of the cavities, there is commonly enumerated therewith a space between two apposed ectal surfaces, the so-called "fifth ventricle," which forms no part of the series, either actually or ideally.
5. On account of its slenderness in man and the higher mammals, one of the primary divisions of the cavity is described as a mere passage of communication, and a like rank is assigned to a division of which the cerebral hemispheres themselves are only diverticula.
6. The fascinations of microscopical technique, the exclusion of the brain from ordinary surgical interference, the difficulty of obtaining the organ in a condition suitable for dissection, and, finally, the not unnatural tendency of writers and teachers to ignore the necessity for more information than they themselves possess, have led to an undue curtailment of the time given to the gross anatomy of the brain. It is, indeed, beyond the range of possibility that a student should be permitted to imagine himself possessed of some knowledge of encephalical anatomy because he can discriminate between corpus callosum and corpus striatum, or between optic lobe and optic thalamus; or even when he can merely repeat a string of sonorous names, notwithstanding, like the "empetatic professors of phrenology," mentioned by Ecker, he has "never seen a brain"—seen it, that is, in the sense of having personally and thoroughly dissected it in a fresh or well-preserved condition.
7. The more obvious features of the larger masses are described and figured in detail, while certain lesser points are inadequately discussed or ignored altogether.
8. The morphological significance of some of these slighter features is so little appreciated, that the descrip-
tion of an orifice in the "lamina cinereus," or the representation of the "third ventricle" without a roof, excites no more surprise than would the enumeration of a larger or smaller number of foramina in the "anterior perforated space."

As the adult human brain is the first and only object of examination, and is taken as the standard of comparison; if animal brains are studied at all, they are often taken as they come, or as anatomical rarities, not selected in accordance with a principle which might indicate the probable degree of their usefulness.

10. The development of the brain is treated only as a division of embryology, and as such is apt to be overlooked until after the time when it might be most useful in aiding the comprehension of the organ.

11. Most anthropotomical accounts of the development of the brain are wellnigh unintelligible to any but the learned anatomist by reason of their brevity, the introduction of elaborate figures, the slight use of diagrams, the attempt to describe or represent at once all the kinds of changes which affect all parts of the organ, and, finally, by the employment of terms differing in character, or at least in form, from those which occur in the account of the adult brain.

12. A few parts have been named from real or fancied resemblances to other portions of the body or to various objects, and as a whole the brain has been treated as if beyond the pale of analogy and literally incomparable.

13. The visible parts, nearly two hundred in number, are mentioned in descriptive anatomy only in their topographical sequence, and the student is expected to master the details presented by the base of the organ, including the nerve-roots, or on a mesial hemisecution, or on transsections at any level, without or no intimation that the parts thus exposed together belong to quite different divisions.

14. The brain has been variously and incongruously subdivided into two, three, or more parts, with apparently no reference to any underlying plan of organization.

15. With some other complex organs, the effort has been made, more or less successfully, to reduce them to their simplest terms; to recognize in each a structural unit which is reproduced with variation throughout the whole. The liver, for example, is a mass of essentially similar lobules, and the lungs consist of innumerable thin-walled sacs, each surrounded by a capillary network.

16. As to the brain, histologically it is said to consist of cells and fibres, and physiologically of ganglia and nerves, or centres and conductors, or "stations" and "projection systems," but the conception of a macroscopic encephalic unit seems not to have been commonly entertained. Moreover, although a segmental constitution of the brain has been more or less distinctly outlined in special papers and in the embryological portions of anatomical compilations, the encephalic masses have been discussed to the nearly complete exclusion of the cavities.

17. The chief obstacle to the early and clear recognition of the simple character of the encephalic unit has been the development of the cerebral hemispheres in man and the higher mammals, and the relative insignificance of the mesial part by which they are connected.

Hence has arisen the idea of encephalic duplicity—an idea which is supported by the pairs of lateral masses called thalami, by the pairs of lateral eminences called lobi optici, and especially by the peculiar physiologic and microscopic divisions of the entire brain with the right and left sides of the body. Thus has it come about, paradoxical as it sounds, that the hindrance to the progress of the philosophical anatomy of the brain has been occasioned mainly by the peculiarities of the very region through which alone philosophy has arisen.

The methods of regarding the brain which have been employed in research and instruction in the anatomical laboratory and lecture-room of Cornell University during the last seven years have been evolved from the study of the organ chiefly as it exists in Embryos, in the Frog and Necturus, and in the domestic cat.

I have to acknowledge indebtedness to two sources—the description and discussion of the typical brain in Huxley's "Anatomy of Vertebrated Animals," and the tabular arrangement of the encephalic names in the eighth edition of Quain's "Anatomy."

The most general statement of the methods recommended may be made in the form of six propositions:

A. The comprehension of the macroscopic morphology of the brain involves the removal of difficulties varying in kind and degree. These several categories of difficulties should be attacked separately, and in the order of (1) their fundamental importance and (2) their simplicity.

B. The arrangements of the solid parts of the brain are more readily perceived and more easily remembered after the relations of the cavities are fully understood.

C. An adequate idea of the circumscription of the cavities involves a distinct recognition of their lining and of the investment of the whole brain.

D. Even when the adult human brain is the ultimate object of inquiry, its detailed study should be preceded, rather than followed, by the examination of embryonic and certain other transitional stages.

E. The arrangements of the encephalic parietes are more readily appreciated if we disregard altogether their organic composition and their direct subservience to mental operations, and view the brain primarily as we might an artificial structure, like a house or a piece of furniture of homogeneous material.

F. In manner to comprehend or explain the various complications of encephalic architecture, by the comparison of the brains of different animals, or at various stages of individual development (ontogenesis), or as hypothetically involved, in geological time (phylogenesis), diagrams should largely take the place of descriptions, even although we may be compelled, provisionally, to assume a knowledge of intermediate steps which may not have been actually observed.

A primary wish of the intelligent student of a complex structure is for a definition which is at once correct, clear, and comprehensive—the concise expression of the most general conception of its constant and essential character.

Excluding the lowest three genera—Branchiostoma or amphioxus, Myxine, and Bdellostoma—the most general macroscopic morphological features of the vertebrate brain are as follows: 1, it is elongated; 2, it is hollow; 3, it is constricted at several points; 4, it is the cephalic continuation of the myelon.

Combining these, we have the following macro-morphological definition of the brain: A segmented, entencranial tube.

The recognition of the segmental constitution of the brain does not involve either of the following matters: (a) the precise number of segments; (b) the identity of their development; (c) the physiological identity of the parts. In a sense absolute physiological distinction between two segments.

The cavity of each segment is primarily and essentially a short, subspherical cylinder, open at either end, excepting the cephalic end of the last.

The primary segmental cavities constitute a single mesial series, but from several of them are produced lateral divisions of the brain.

These diverticula may be formed, by budding, at a very early period, as, e.g., the optic vesicles; or later, as is probably the case with the so-called optic ventricles of frogs and birds. The lumina may persist through life, as in the latter instance; or be obliterated, as in the former, where they form the optic tracts. In both cases they are comparatively simple in form, and in some animals (Necturus, Petromyzon, etc.), this is true also with
the most cephalic diverticula, which become the cerebral hemispheres and lobus efactorii. In man, however, and the mammals generally, the cerebral diverticula become disproportionately large; their cavities, the so-called "lateral ventricles," are very irregular in form, and so much more extensive than the primitive mesial cavity from which they sprung that the latter is sometimes overlooked altogether.

But it must be borne in mind that in frogs and birds the lateral masses and cavities constituting the optic lobes are also both large and complicated. Indeed, prejudice aside, they might well be designated as "hemispheres" and "cornua." Whatever may be the actual directions of these diverticula, all should be reduced to one normal position, extending laterally at right angles with the mesial line representing the primary cleidian series.

The simplest representation of the encephalic unit is as a single thin-walled cavity, as it is in the early embryonic stages. Secondly, and in accordance with some facts of comparative anatomy, but still from the purely macro-morphological standpoint, there are three communicating cavities—one mesial and two lateral. Finally, the cavities of the brain as a whole, from the histologico-physiological standpoint, we have two lateral masses conjoined by transverse commissures. In more concise verbal form, the embryological idea of the brain is unity, the morphological idea is triplicity, while the physiological idea is duplicity.

The cavities of normal adult mammalian brains are comparatively stilette, and hardly more than traces of what existed in their own early stages and presumably in the remote ancestors of mammals, as in the amphibia of the present day. Hydrocephalus is the retention or exaggeration of this normal embryonic condition, and brains thus affected, if properly preserved and examined, may very clearly illustrate the manner of circumscription of the cavities.

In the brain, as in other regions of the body, the teleological importance of a part may be no index of its morphological significance, and may even be inversely thereto.

In addition to the usefulness of a knowledge of the relations of the cavities in facilitating a comprehension of the plan of the brain, they are, very nearly a guide to the distribution of the ganglionic centers, and the course of the fibrous conductors and channels of blood-supply. Intrusions of vascular pleuresies occur at various points, but the larger vessels rarely invade the cavities. Only in the mammals, and perhaps not in all of them, is the brain privacy disturbed by that most unsubstantial union of the mesial cavity of the pig can be obtained in all stages of development, as has been so well illustrated in the work upon human physiology by the distinguished professor from whom many of my hearers have gained their knowledge of that science.

The remaining vertebrate class, the amphibians, including the frogs, toads, and salamanders, fulfills, as a whole all four of the conditions named above. The advantages presented by the frog's brain have been admirably described by Wymans, and may be more categorically stated as follows:

1. The variety of change from wide in size, differ much less than the other higher animals, so that it is completely hidden by other. 3. All lie in the same plane. 4. The cavities are relatively large. 5. The varieties vary little in thickness. 6. While all the primary components of the brain are present, there are but few special additions or modifications to distract attention from the general plan. 7. There are three "optic nerves" and those of the mesencephalon—one mesial and two lateral, as in birds.

In the view of all these excellences and the very obvious advantages for general dissection afforded by a creature which is readily obtainable and wholly inoffensive, whose tissues are coarse, and whose organs are readily separable, the very skin being, as it were, only "based on," to criticise the frog as a subject of elementary anatomical study is to deride a laboratory pet. Nevertheless for beginners the frog's brain is objectionable, because (a) the pleuresies are almost wholly wanting; (b) in common with the other Anura, there is, in the adult, a close connexion of the lobes "efactorii" which is anomalous and misleading. I say misleading, because it only not puzzles the beginner, but also, inasmuch as the hemispheres remain separate, there is formed a sort of nervous ring, and even the late Jeffrey Wymans, who made so few mistakes in observation and interpretation as to merit the title of the anatomical George Washington, compared it with the cephalic ring of some invertebrates.

In view of these considerations, would it not be well to disconnect the olfactory lobes when a frog's brain is first:

1 The physician who has lost a patient in consequence of the lodgement of a grape-seed in or other natural constipation of wholesome food in the alimentary canal of the frog, for Magendie, may endeavor to reconcile the calapsy with popular belief, but will more likely look forward to the terrified expression of the "nervousness of maternal sorrow," as ceded by being an element of human structure.
examined, and should not more frequent and systematic use be made of the large salamander *Necturus* already mentioned?

But even the *Necturus* brain has its drawbacks, and it must be admitted that a great desideratum of the teacher and student of embryology; namely, a brain constructed on the general pattern of that of *Necturus*, but with the firm texture and more distinct cerebellum of the frog, and at least as large as the brain of the giant Megalobatrachus of Japan.

THE RECIPROCAL ATTITUDE OF THE MEDICAL PROFESSION AND THE COMMUNITY.

By ALEXANDER HUTCHINS, A.M., M.D.,

BROOKLYN, N. Y.

There is a medical science, but if medicine were a science only there would be fewer medical schools than now exist.

The former part of this proposition has been flatly denied. The impression is prevalent that while much learning has been amassed in medical research, the conclusions are so untrustworthy as a basis for future observers, that, in the catalogue of the sciences, medicine is to be classed among the empirical, and not in the exact.

Although the scope of intellectual activity has varied, there have been scholars in all ages, and in each era the lines have been sharply drawn between those who have wrought into new forms truth that has been revealed, and those who have labored in the discovery of truth to which the world had, hitherto, been a stranger. The scope of the sciences has been enlarged; investigation has developed an orderly arrangement of facts and principles, and knowledge, in any special line, must be elevated into the rank of the sciences.

Human anatomy is a science, and, in its orderly classification of structure and relation, was a science long before the dependent science of histology unraveled the closely woven web that held so many mysteries in its fast embrace; before physiological science lifted the veil and disclosed the inevitable necessities of related structure; before chemical science touched with her magic wand the sealed volume where lay inscribed the hidden processes of waste and repair; before pathological science began her study of the myriad variations from the ideal type of structure, and of the utmost bounds where the interrupted harmony of process becomes record, beyond which is destruction; before the science of embryology all but touched the confines where the creative force starts the complex human mechanism in its infinite reproduction; before comparative science demonstrated the unity of animal organism; before biological science grouped all living organization, to make clear the intimate similarity that exists in all structures inferred with the element called life.

Medical science assumed her unique place among the sciences when the facts and phenomena, evoked by biological research, were made the basis of investigation, whose purpose is to prolong the vital process and arrest the untoward influences that perpetually threaten its extinction. This is her distinctive mission. Though some names are inseparably connected with the beginning of certain movements that have become classic, the body of medical science is the slow accretion of the centuries, and the contributions to its learning are too numerous for the historic pen. The results of yesterday are the alphabet of to-day. The unproven is rapidly discarded, the good is improved upon and becomes common property. By the very genius of the science this history of progress and change must always be repeating. The days rapidly hasten on when the names of McDowell and Von Graefe, of Keith and Sims will be prominent only as landmarks.

The discoveries made by Jenner, Ehrenburg, Dujardin, Schwann, Pasteur, Lister, Koch, Lacerda, Ziehl, Raschus, Semmelweis, Virchow, and many others, have removed our doubts as to what lies beyond; but their far-reaching results are the product of the present decade of investigation, and we stand but at the threshold of these directions of biological research.

The attitude of the community toward scientific study is, primarily, that of antagonism. There are many years, but none so wonderful as the present, between the persecution of Galileo and the onslaught on vivisection; 1616 has somewhat of kinship with 1884. Popular government has never initiated any movement to promote research, for that implies a cultivated sentiment among the voters, and the English-speaking nations have done almost nothing in the way of State appropriations for scientific study. Germany, France, Russia, Holland, Belgium, and Italy are, almost exclusively, the originators of the later methods.

The most that has been done in England and the United States has been done by those men whose capacity for scientific discovery has been accompanied by the possession of private fortune; the remainder has come from work incidental to the occupation of professional chairs. In this country neither the professional nor the layman has any knowledge, any State has done the first thing to further scientific research directly. Much has been done for industrial education, and a great deal of research is really carried on under cover of State and government appropriations, but all is of secondary moment to the powers that be.

Scurvyly any provision has been made until recently for biological science in our institutions of learning, beyond elementary instruction. But these facts do not prove the basis of complaint. The scholars must always be the select few. The bacillus of malarial fever might hollow out the historic niche for its discoverer, though the discovery would not sell for a dime.

The cultus of medical science must continue to share the experience of all original investigation, and remain a personal factor among the diverse directions of human industry. They who cull the flowers, enjoy the fruit, reap the harvest, or sell the crop, are of different mind and another station than they who till the ground, plant the seed, and nurture the same till it comes to maturity, through recurring seasons of sun and snow, till the sturdy limbs are shelter and refreshment to the unthinking life that recks not of its benefactors.

There is an art of medicine and its multitudinous liberties the fruitfulness of its pursuit.

In 1880 the States and Territories of this country enumerated as either physicians or surgeons a proportion of 1 to 685; in the State of New York a proportion of 1 to 548. These salutary, health-forecasting, and longevity-producing statistics stamp the effete and tottering governments of Europe with the die of derision in their infamous disregard of human comfort; for while the proportion of doctors to population in Switzerland is 7.06 per 10,000, in Italy 6.10, in Hungary 6.10, in England 6, in Austria 3.41, in Germany 3.21, and in France 2.91, the United States, with their 17.1 per 10,000, have consummated what Berkeley foresaw, but did not dare to write—"Westward the doctor's empire has full sway."

The causes of this disproportion are complex and do not rest on the surface. A nation of livelihood the profession of medicine is attractive, and little wonder need be that its ranks do not on this account suffer depletion.

From the social standard the profession elevates the man, no matter of what stuff he is made, if he does not ostentatiously disgrace himself. The fact is patent, that this impulse is certainly not insignificant in the choice of a future.

Combining the certainty of livelihood and the assurance of position it will, in this day, hardly be questioned

---

1 The anniversary address delivered before the Medical Society of the State of New York, at the seventy-eighth annual meeting, at Albany, February 6, 1884.
that no other walk in life holds out such positive promises of immediate reward and of continued permanence as does the medical profession. There is a larger success per thousand, with less bankruptcy, with freer and more varied opportunity than belongs to any other class, in any of the lines of occupation along which men grope their way through time. In the present, in this presence, to relate how gentle the acclivity that appears, how wide-open the portals that invite, how roseate and verdant the paths that gladden, how radiant the sentinels that summon and assist the novitiates on their way to these easily acquired places of esteem and support. The restrictive barriers are so loosely set up, and the final test of fitness so daintily supplied, that the former are cast down as easily as the latter is overcome. There is not even the seclusion of an open secret; there is the common knowledge among medical men that their ranks are recruited continually with men who have accomplished the distance in accord with the most perfunctory of formalities in the minimum of time. Whether this is wise or unwise, right or wrong, is not the question. In this paragraph. The facility of admission is the pertinent fact.

The time was, and the fiction has not wholly faded from common speech, when law, medicine, and theology were denominated the learned professions, as distinguished from the professions of the army and navy, because a university education was a prerequisite to these speculations. Teaching was then the principal and almost the only contribution of special knowledge, this discrimination does not hold. The profession of medicine has not kept her distinguishing place. Her recruiting sources have been so many, her safeguards of loyalty have been so weakened, her probationary tests have become so insignificant, that however smile-provoking may be the mention of the wig and cane, and the symbolism of the duchy and of the knight and the prébendé chevalier, and the proportion of medical men who are in accord with the medical profession at its best, both in knowledge of its results and in capacity to do, is rapidly lessening with the years.

There is an inconsistency in all this which does not mitigate the complexity of the problem. The profession has never lost sight of the sacredness and importance of its trust—at least if spoken words are not hollow and meaningless.

If these statements misrepresent the facts, no charity should be permitted to condone the mistaken zeal that would abuse the opportunity of this platform and cast slanders upon the profession; but if the statements are true, the safer plan is to examine the facts and is privileged to follow up the consequences.

The profession of medicine, at its best and in its ideal condition, includes a body of men who offer to serve the community for a consideration. The end of all medical learning is to make sick people well, to assuage the discomforts of the incurable, and to promote the euthanasia. But nevertheless personal time and labor are furnished, on which a price is set.

The matter of compensation for medical services has been handled with many degrees of sensitiveness, but the fact remains that the arts of medicine are practised as a means of livelihood. Yet it is contrary to the popular understanding, but still the fact that the cases where money is amassed from the practice of medicine are very exceptional.

The sense of loyalties, however, to the heritage and mission of medical learning has been so instinctive in its history that any suggestion of its trade instincts has been met by prompt rebuke.

But this has been questioned that skill in differential diagnosis is the safe basis of treatment, and varied resources in medical art lead most readily to the best results; and the faithful student in the profession is the one most keenly alive to the importance of both. On the other hand, it is asking too much of credulity to believe that the attitude of the profession is friendly to the community when the doctorate puts into so many undisciplined hands the medical arts which are as potent for evil as for good. Humiliating and unsavory though it be, the pregnant fact holds true that, coupled with that large body of men who base their art on principles which have survived criticism, and whose livelihood is a legitimate product of their worthy and acceptable service, there is another and larger class, known to the community by the same name, with equal protection under the law, who (described lately by an influential medical journal as "hangers-on of whom any party would be ashamed") are a standing menace to the community, which, accepting as a criterion, and whose livelihood in the race, gives to all alike its patronage and its support.

The community, however, is not slow to accept the offers of mercy, for while it submits patiently to all that is ordered by the profession, takes all its medications, undergoes all its operations, awaits the results of all its experiments, and unhesitatingly believes everything it says, and quotes it, more or less correctly, for the neighborhood or the benefit of the community, in its charity toward all, does not allow the profession monopoly in the practice of medicine, but with its faith in drugs, and measuring their efficacy by the violence of their operation, it swallows on bare printed promises $60,000,000 in proprietary medicines per year, and assists the fortunes of drug dealers to the extent per annum of $80,000,000 more.

On the other hand, the profession has no just complaint against the attitude of the community in the exercise of its law-making functions. I am not aware that any legislature has ever initiated any statute designed to restrain the freedom of the profession.

The President then spoke of the reciprocal relations between sanitary science and the community, and said that if sanitary science really contains the "promise of the potency" its advocates claim, and if its results should become formulated into laws for the sure protection of large communities, the reciprocal attitude of the medical profession and the community must, in the meantime, have undergone many radical changes; so radical, indeed, that the imagination might snap in the stretch to compass them; so radical, indeed, that the "genuineness" of "Othello's occupation" would be nowhere in the immense knowledges that vacancy that once was alive with the busy ministry to ills, that then shall be but a dismal retrospect.

With reference to

TEACHING AND CONFERRING DEGREES,

the speaker believed that one may be justified in parting company with the practice of the period, and demand, in the interest of medical science, for the maintenance of professional honor, and for the protection of the community, that the teaching and degree-granting authorities be not one and the same. Let the community, through its law-makers, legislate into control an acceptable judicial body, in which shall rest the decision of the fitness of candidates to assume the responsibilities.

No man has an inalienable right to practice medicine. He can choose to do so, but the public may adjust the tests of his fitness.

It is estimated that three-fourths of those enumerated as physicians and surgeons are, up to the limits of their individual competency, applying to the healing of human ills the best methods of experience, based on the knowledge derived from scientific research.

The community is as incompetent to decide upon the merits of the former as it is capable of being deceived by the skilful manipulation of the remaining one-fourth. The physicians who are floundering through the uncertainties that ignorance imposes, or who abuse the confidence of the community for purposes of gain; who will take any other course than to tell the truth and employ
the most experienced devices to secure the speediest results, are beyond the reach of all codes, whether of human or angelic contrivance. And yet the profession, in its efforts to gain the confidence of those of a free heart and a God-speed, must consult with them on equal terms, and, in an emergency, defend them in the public confidence.

Read McMaster's delightful description of the doctor in 1784; see the same men as they are adapted to the social relations in varying communities all through the back and side washed with water to make them acceptable by every heart-stone; prepare, to fill their places, men whose accomplishments shall be the test of fitness; and, with the assurance that character is the result of responsibilities well met, and that character alone is instrumental to make the educating impress on the community, the day need not be far distant when the medical profession shall be in the wiser confidence of the community.

There is a laudable pride in occupations, and its basis is the consciousness of doing a useful thing well. To defend his heritage is the chivalrous duty of the scholar.

**Original Articles.**

**TWO UNUSUAL CASES IN OBSTETRICAL PRACTICE.**

**By William C. Wey,** M.D.,

**Elyria, O.,**

The title of this brief paper may be misleading to practitioners of exceptionally large experience, who are familiar with nearly all the phases which are assumed in the puerperal state. It may be misleading also to physicians who, with experience in a more limited number of cases, have been brought in contact with so many of an anomalous character as to have acquired thereby a wide range of observation and study. The term unusual is applied in the sense in which it occurred to me to employ it in the description of the cases which I am about to relate, inasmuch as my observation had never before included such phenomena as were then presented.

**Case I.** Concealed accidental hemorrhage, complicating labor at term, resulting in the death of the fetus and the alarming prostrations of the mother.—Mrs. W. —, an American, thirty-three years of age, married at nineteen and twice born, in single labors, to seven children at maturity, four boys and three girls, with the exception of her third child, a girl, which was born at seven months and lived. She expected to be confined with her seventh child on or about August 16, 1883. Her health during pregnancy, as always before in this condition, had been good, and she gave constant attention to the management of her household affairs. Suddenly, at five p.m., August 6th, while sitting in a chair, and simultaneously with the vigorous and painful movements of the fetus, she experienced a sense of extreme pressure, attended with a sinking and sickening sensation in the situation of the womb, low down and in front. She became faint, nauseated, and cold, and was compelled to lie down and call for aid. The child was expelled, with no apparent cause, and her symptoms, which to her friends who rallied to her assistance indicated approaching labor, prompted the calling of a physician, and in an hour from the moment of the attack I was in attendance. The woman was in a state of collapse. Her hands and feet were cold and clammy, face pale, respiration sighing, pulse low and feeble. She lay on her back and complained of pressure in the lower part of the abdomen. Examination of the surface to which the pain was referred afforded no explanation of the symptoms which were so manifest. It was not unduly tense, tender, or irregular in outline. Digital inspection or the os uteri elicited no evidence of approaching labor. My first thought was that in some unaccountable manner the womb had been ruptured, and that the symptoms of collapse, so conspicuously present, were due to the ruptured uterus. The patient's relief from the rupture of the uterus could scarcely exist, except as the result of violence, accidental or otherwise, which was improbable and soon shown to be impossible. Prompt restoratives were employed, such as heat and friction to the extremities, hot bottles and bricks wherever they could be applied, warm spirits by the stomach, and to relieve the distressing and pernicious feeling of discomfort in the situation of the uterus, morphine was injected hypodermically. These measures proved successful at the end of an hour and a half, and the natural warmth of the body revived. Sooner, however, the injection of morphine accomplished the purpose expected of it, and in less than half an hour the patient obtained relief from the symptoms which caused her so much suffering and uneasiness. When animal heat had been fully restored, signs of labor appeared and rapidly developed, and at half-past ten o'clock, five and a half hours from the seizure, she gave birth to a large, dead male child, the waters escaping a few minutes before, without stain of blood. The cord separated and corded, with over hastening and manipulating the uterus through the abdominal walls to favor the escape of the placenta, a discharge of coagula took place, which nearly filled a large chamber-vessel of the capacity of two quarts. The placenta followed immediately, and the uterus contracted well under the hand. The patient was faint and prostrated. A bandage was applied, the head and shoulders were depressed, stimulants given, air admitted around the bed, and the fluid extract of ergot administered in quickly repeated doses. No further hemorrhage occurred. The patient presented the appearance of an exanguinated person, and remained four weeks in bed, with signs peculiar to that condition such as rapid and feeble action of the heart, extreme pallor of the face, lips, and ears, inability to rise from the recumbent position without threatened syncope, humming in the jugulars, great feebleness of voice, lowered temperature, etc. At the end of seven weeks, although able to ride out, she presented the appearance of decided anemia, and remained greatly deficient in strength.

I am moved to report this case because, as already mentioned, it is the only one of its kind which has occurred in my practice, and because I failed to appreciate its character until explanation of the symptoms was afforded in the escape from the uterus of a large accumulation of coagulated blood, in advance of the delivery of the placenta.

Burns, quoted by Churchill, refers to the accident under consideration as follows: "In such cases the effusion is accomplished with dull internal pain at the spot where it takes place. The pain is something like colic, or like the pain attending the approach of the menses. The part of the womb where the extravasation takes place swells gradually, and in a short time the uterus feels larger. If the quantity be considerable, the size increases, the uterus is felt to be firmer and taut, as well as larger, the strength diminishes, and some faintings may come on. In course of time weak, slow pains are felt, but if the injury be great, these decline as the weakness decreases. They may or may not be attended with dilatation of the coagula from the placenta." The symptoms correspond essentially with those which were met in the case described, except that abdominal palpation failed to detect any apparent deviation from the normal size and smoothness of the gravid uterus, and the rapid completion of labor, when reaction after hemorrhage was effected, are unlike the signs and symptoms of accidental hemorrhage described by the author. Partial explanation of the failure of the test as applied to the abdominal surface is afforded in the large size of the woman and the thickness of the parietes;
also in the presumption that the situation of the placenta and the hemorrhage may have been posterior and between the fetus in front and the uterine wall behind, thus, while adding to the bulk of the organ, in no way altering its symmetrical shape under the hand. My impression is that this test is not as reliable as would seem to be indicated, except in cases favorable to the production of the placenta, which give it significance, and reference to Dr. Goodell's summary of symptoms, to be quoted, sustains this position. The faint and collapsed condition of the patient cannot, as a matter of course, be attributed to hemorrhage alone. The influence of shock to the nervous system, caused less by bleeding than by the pressure of the comparatively small quantity of liquid, a stream from the body than undue stretching of the muscular fibres of the uterus in such cases, may be overlooked. It is a striking fact, not satisfactorily explained, that "accidental hemorrhage," as described, "most commonly occurs in people who have borne many children." Dr. Robert Barnes attributes the separation of the placenta in the cases of such women "whose constitutions are worn by sickness or poverty, and whose tissues, therefore, are badly nourished, wanting in tone, tending to atrophy or degeneration." This physical state will not apply to the case reported, which took place in a well-nourished and healthy woman in her 20s, whose energies had not been unduly reduced by childbearing, disease, or the drain of nursing. I will not stop to consider the "causes" of this "accident." They are many; some probable, some demonstrable, and some quite imaginary. In the case under consideration no assignable cause appears for the hemorrhage.

Dr. William Goodell, of Philadelphia, quoted by Dr. Dawson, the American editor of "Barnes' Obstetric Operations," published a paper on "Concealed Accidental Hemorrhage," in the American Journal of Obstetrics, in 1869, in which the peculiarities of one hundred and six cases were considered. An analysis of these cases shows the prominence of the following symptoms in the order in which they are presented:

First, an alarming state of collapse; second, pain in every degree of severity; third, absence or extreme feebleness of the pains of labor; fourth, marked distention of the uterus; fifth, before the lapse of many hours a show of blood; sixth, an accessory tumor in uterus or abdomen; seventh, tenseness of the membranes; eighth, rapid dilatation of the membranes and the appearance of blood in the liquor amnii.

A word only on the subject of treatment in these cases. According to recent writers, delivery should be accomplished as speedily as possible. Dr. Goodell lays down the following axiom: "(a) That the greater the hemorrhage, the greater will be the syncope; (b) that the pains of labor will become feeble in direct proportion to the severity of the collapse; (c) that consequently they are generally absent in the worst cases of hemorrhage, and cannot be aroused by the most powerful stimulants and oxytocics so long as the uterus is over-distended; (d) but that, when the membranes are pierced, the vital contractility of the uterine walls reasserts them, and usually provokes their organic contractility, unless the system be too far depressed." In the case under review the hemorrhage was large and the shock or collapse correspondingly great. This condition took place without the occurrence of any signs of approaching labor. The establishment of reaction aroused at once uterine effort, which was as prompt and forcible as with the other cases, and caused the speedy extrusion of the child, contrary to axioms (b) and (c) in the foregoing quotation, and this, too, while the membranes remained intact until the head was just about to pass into the world.

A review of the subject of "accidental hemorrhage," or, as Dr. Goodell designates it, "concealed accidental hemorrhage," makes the case reported among the most favorable in that grave form of complication in labor which can be presented to the practitioner, except where bleeding to a more limited degree falls short of destroying the life of the fetus. The prompt accession of labor after the hemorrhage, the integrity of the membranes nearly up to the time of the escape of the child's head through the external parts, the rapid emptying of the womb of clots by external manipulation, the speedy expulsion of the placenta, and the hasty and persistent contraction of the uterus, were elements in the case by which the safety of the mother was assured at the crisis of delivery, and she was prevented from reaching a more dangerous degree of prostration from loss of blood and the shock of the extraction of the child.

Case II. Death of fetus at about the seventh month; labor at term and rapidly advancing, vertex present; subsidence of uterine effort, caused by complete separation of the placenta, which was extracted by the hand; delivery of the child by turning; shock; peritonitis, and death in four days.----Mrs. Mary A., an American, born in 1843, and married at twenty-two, had given birth at full term to seven children, three boys and four girls. No accident or embarrassment of any kind took place during pregnancy or in childbirth, and her offspring, with one exception, a female child, who died of meningitis when three years old, are in good health at the time of making this report. Mrs. A. never having missed a child, became very anxious at the eighth month. She delivered on January 1, 1883. Pregnancy advanced without noticeable event, quickening was perceived in the middle of May, and motion was felt from that time almost daily until early in August, when without apparent cause it ceased entirely. Her general health remained unchanged as time advanced, and during the evening of October 6th, labor set in, and I was called and found the uterus as large as a child's fist, the uterii as largely dilated as a silver dollar and soft and yielding. The membranes protruded in great size and force at each pain. They were very dense and nearly filled the vagina. It was impossible, even at intervals between pains, to feel the presenting part of the fetus. I attempted, without success, to rupture the membranes with my finger, and resorted to the points of a pair of scissors for that purpose, and let out at least a pint and a half of clear fluid, which afforded only natural odor. The finger then came in contact with the overlapping cranial sutures of a dead fetus encaged in the inferior strait. The evacuation of the amniotic sac was followed by an abatement of pain. But an hour later, in a moment of rest, a sudden, severe, and depressing sensation was complained of in the left iliac region, which for thirty minutes suspended all uterine effort. The situation of suffering became quickly sensitive to the touch, and the patient was obliged to assume a fixed position, lying on her back and a little to the right side with her extremities, particularly the left thigh and leg, well drawn up. The head of the fetus did not recede, and no change was marked in the uterine tumor felt through the abdominal walls. The application of hot cloths to the seat of suffering soon afforded relief, and the case progressed slowly but satisfactorily for two hours, the patient meantime getting brief periods of sleep, when she spoke of feeling faint, and it was discovered that a slight flow of blood was issuing from the vagina. Examination through that channel failed to find any presenting part of the fetus. My finger, pushed to its utmost limit, passed, apparently, into an empty womb. I suspected that the uterus had ruptured, and introduced my hand into its cavity, which came immediately in contact with the thickomentum, swollen, and lying loose in the situation the head had occupied a short time before. This was extracted, globular in form, reduced in size, and firm in texture. Again inserting my hand and carrying it well up, I reached the feet and rapidly turned and delivered the child, which appeared to be a seven-months' fetus. The bones of the head were
detached and loose, the scalp and other portions of the cutaneous surface were dark and decomposed, and the skin slipped from the feet and ankles as I made traction, in the act of delivery. The uterus contracted promptly under pressure and manipulation with the hand through the abdominal coverings, and no blood followed the removal of the child, which took place at five o’clock on the morning of October 7th. The patient bore the entire operation, removal of placenta and fetus, which lasted only a quarter of an hour, with great fortitude.

Soon after delivery nausea and vomiting occurred, and pounded ice and drink of every kind was rejected by the stomach. The bowels distended, the abdominal surface became tender, the temperature ran up to 103° and 104°; the pulse rose to 120, 130, and 140, the catheter was constantly required, hiccup followed, and the woman died ninety-four hours after delivery from shock and peritonitis.

The treatment pursued can be mentioned in few words. The stomach was spared the reception of supporting measures, which were supplied by the rectum and well borne, such as milk and whiskey. Pain was overcome by the hypodermic injection of morphone. For a time I placed a hot bottle over the entire abdomen, but exercised an apparent controlling influence over the nausea, and had it not been for the ignorance of a self-sufficient nurse, who disregarded my instructions, and withheld for a number of hours the injections of milk and whiskey in the rectum, I felt as if the patient would have rallied from her extreme depressed condition. This exhibition of stupidity occurred, unfortunately, just at a time when the stomach had been composed for more than fifteen hours, and when reduced temperature, improved pulse, and quieter respiration filled me with hopefulness in view of the termination of the case.

It is to be regretted that the placenta was disposed of, soon after its removal, in such a way as to prevent further examination of it, by which its separation from the maternal surface had been effected. It should be mentioned that suspicion of syphilis, as a factor in causing the pathological changes which were wrought in the structure and functions of the placenta, could not be entertained in this case.

The questions connected with this narrative are interesting and of value, first, because the expulsion of the placenta before the child may occur as an accident in labor, without necessarily giving rise to hemorrhage, though putting in jeopardy the life of the child, according to the time which elapses between the natural or artificial removal of the after-birth and the birth of the infant; and again, because the manual extraction of the placenta, in case of placenta previa, may prove the readiest and most scientific means of controlling hemorrhage and saving the life of the mother.

We are indebted to the genius of Sir James Simpson for an exposition of the effects, as regards hemorrhage and its attendant dangers, of complete separation of the placenta in labor, before the expulsion of the fetus from the womb. "Paradoxical as it may appear," using his own words, "there are sufficient grounds and facts for believing that when the placenta is separated slightly and partially, the chance of fatal hemorrhage to the mother is greater than when the disunion of the organ is entire and complete." He adds, in another place, "I believe I have collected a sufficient number of data to prove that, when the disjunction of the placenta from the uterus is perfect and complete, the degree of material hemorrhage which occurs is, in general, exceedingly slight and trifling, or it is altogether arrested" ("Simpson’s Obstetrical Works").

The cases presented have features in-common, such as manifest local and general symptoms at the time of partial or complete separation of the placenta. A question may be raised in respect to the propriety of rupturing the membranes, in the second case, when labor seemed to be proceeding so rapidly. As stated above, this was done to ascertain the character of the presentation. It is quite likely, if the membranes had not been ruptured and the continuance of pains, as they were then advancing the case, would soon have terminated labor by the natural method. The discharge of one and one-half pint (estimated) of liquor amnii permitted the uterus to shorten its fibres on its contents, consisting of a dead fetus and a diseased placenta, the latter holding only partial and slender attachment to the maternal surface. This contraction detached the placenta, which had withstood pressure as long as uniformly maintained by an evenly distended womb and a superimposed quantity of bland fluid; hence the accident under consideration. It would have been in the line of allowing nature to take its course, whereby the reminder of "medlesome midwifery" might have been avoided, if the membranes had been suffered to remain intact as long as they were able to resist the pressure which urged them through the os uteri.

In the second case signs of rupture of the uterus were strongly presented, such as the immediate occurrence of a severe and depressing sensation, amounting to pain and tenderness, of the bladder and sigmoid attachment to the uterine effort, for a period of thirty minutes. These signs were dispelled, labor was resumed moderately for a couple of hours, when they were again and much more formidablely established by faintness, the appearance of blood in the vaginal discharge, and the recession of the advancing head. The uterus emptied by the delivery of the signs of rupture and held in a rent in the uterus, too limited in extent to allow any part of the fetus to escape in the abdominal cavity, and evading detection by the hand, in the process of turning, as mentioned by writers, would have produced precisely such symptoms as were developed in this case. I am compelled, however, to exclude rupture as an element in this history, for the reason, chiefly, that it is not demonstrated with my hand twice in the cavity of the uterus.

A CURIOUS GUN-SHOT WOUND.—Dr. A. R. Platt, of this city, reports the history of a curious case of gun-shot injury which was under his charge. "The patient," he writes, "was placed in my private hospital, at Chefoo, North China, by Dr. B. C. Rogers, Passed Assistant Surgeon U.S.S. Monocacy, on September 22d, who furnished the following report of the case: 'Name, Olaf M.—landsman, U.S. Navy; age, twenty-three; native, Norway; disease, vulnus sclopetarium; September 11, 1885, off Rose Island, Coroa. The patient, while pulling in one of the ship's boats, making the regular 2 P.M. trip to the settlement ashore, was shot by one of a party of marines belonging to the vessel and then at target practice on Rose Island. (The ball—conical Hodgeski; weight, 360 grains—struck the edge of the target, lost 20 grains from its point, and passed at a right angle in the direction of the boat.) The ball entered the right temporal region above the zygoma, and about one inch behind the supra-orbital ridge, passing obliquely across the intervening tissues and bones, and lodged underneath the skin in front and above the angle of the lower jaw on the left side, from whence it was shortly after cut out, and the wound dressed with carbolic acid water. The patient showed little evidence; pulse ranges from 52 to 60; voids urine, and bowel moves naturally. Takes liquid and semi-solid nourishment.' The patient made a good recovery, and was discharged cured in about two weeks.
With regard to the bearing anteflexions have upon dysmenorrhea, the views of the more experienced observers appear to have undergone considerable modification within the last few years. Formerly it was quite generally believed that anteflexion, especially when the angle was anywise acute, stood in the positive relation of cause to the menstrual distress. It is now recognized that the uterus canal formed a valve-like barrier to the exit of the menstrual secretion, hence the painful contractions of the uterine muscular fibres, in the effort of the organ to rid itself of the imprisoned fluid.

An objection to this theory, among others, is that a great number of women who have anteflexion of the womb, even when the angle is anywise acute, do not suffer with dysmenorrhea; nor, in those cases which do so suffer, does the disease always yield to the straightening of the organ; while, on the other hand, dysmenorrhcea associated with anteflexion is sometimes cured without straightening the uterus. These facts, together with many others which need not be mentioned now, tend to show that when the two conditions coexist they do not necessarily bear the relations of cause and effect, but rather those of coincidence. My own observations lead me to the corroboration of this latter conclusion.

But there are other complications of dysmenorrhcea, which beadcloud and overshadow the real malady, in such a manner as to render the primary suffering insignificant, or of quite secondary importance, in the same time, they obscure the diagnosis and are misleading as to treatment. I refer to those mysterious reflex phenomena which have been so aptly named hysteroneuroses. The value of mechanical dilatation in these cases is, in my opinion, very great. I have seen a patient, thirty-five years old, married but sterile, who for a number of years was obliged to take to her bed several days during each menstrual epoch on account of both pain and nausea, but particularly because of the nausea, entirely relieved of all discomfort by dilatation of the cervix—this, too, when there was no flexure or other malposition of the womb, nor tenesmus, but great hyperesthesia at the internal os, which was the sole discoverable fault.

That form of dysmenorrhcea which is usually described as spasmodic, and which is, moreover, generally complicated with a reflex neurosis of some form or other, offers an especial field for the employment of the dilator. The true pathology of these cases may be difficult to explain, but their most prominent symptom, that of hyperesthesia at the inner os, and when this sensitive point is reached or touched by the dilator it is almost sure to provoke a manifestation of the same reflex phenomena, though in a less degree, which occur at the ordinary menstrual periods. These latter, however, are usually of short duration, generally subsiding immediately upon, or very soon after, the withdrawal of the instruments.

Whatever be the causes of this morbid sensibility at the point described, it seems quite certain that it plays an important part in the etiology of the form of dysmenorrhcea in question, for when it is overcome or blunted by the use of the dilators the malady itself is either benefited or removed. So, too, with the reflex phenomena, such as intense nausea, gastralgia, headache, hysteria, and other neuroses, for they also subside with the same promptness when the dilator has accomplished its work. Whereas, therefore, the menstrual week has heretofore been ushered in with backache, headache, nausea, and a most distressing general malaise, which has finally culminated in agonizing pain in the pelvic organs, the whole menses then is reduced to ten days, we now find that the subject is often taken with the flow unawares, even while on the street or at an evening party, and passes through the entire epoch with very little or no physical suffering. This is no fanciful sketch or exaggeration of the facts, for I have seen the like over and over again, and am constantly meeting with parallel cases in practice—cases which have resisted all the usual
measures adopted for their relief, but which have readily yielded when dilatation has been thoroughly and systematically employed.

It is scarcely necessary to remark that there is nothing novel in the employment of mechanical dilatation for the relief of dysmenorrhea. Mackintosh dilated the cervix as early as 1806, and since that time it has been employed by Sir James Y. Simpson for various conditions and with variable results. Priestley, Ellingeri, Busch, and others have recommended it, and have also devised various instruments to facilitate its success. Their instruments were, however, introduced closed and then forcibly separated, spreading open the cervix by the divergent force of their branches. Then came the days of the sponge-tent, whose efficiency the elder Storer praised so highly; next the sea-tangle, and finally the tupelo tent. The method of dilating the uterus by tents is, however, open to the dangers of septic infection, hence numerous instruments have been devised, having for their object rapid or gradual dilatation without the dangers of sepsis. Peaslee first, then Hanks and some others in this country, and Lawson Tait and Hegar abroad, have presented us with graduated uterine dilators, made of metal or hard rubber, most of which answer admirably the purposes for which they are designed. Their methods of use are quite alike and may be briefly described as follows: The patient is placed upon the table in the semi-prone position, and the cervix is introduced. The cervix should next be fixed with a double tenaculum, or a voisellum. I lay stress upon the method of the fixation of the cervix. The single tenaculum is not firm enough, and, besides, will often tear out during the process of dilatation. Emmet's or Hanks' double tenaculum are well adapted for this use, and if I should express a preference for Emmet's instrument, this is simply because of being more accustomed to its use. When the cervix is firmly secured one of the smaller dilators is introduced and carried through the internal os; if this passes readily it is immediately withdrawn and the next larger size carried up, this process being repeated until considerable resistance is met with, when the dilator is allowed to remain a few moments in situ before attempting the next size. The extent of the dilatation required will of necessity vary considerably in different cases, but as a rule I should say that it need not be very great, particularly in cervices of large calibre, and this statement is based upon the observation of cases which I have attentively watched. Generally and within certain limits, as the dilatation advances, which circumstance indicates that the stretching need not be extreme to obtain relief. This process of dilatation may quite often be accomplished without the aid of an anesthetic, but now and then the hyperesthesia at the internal os is so great, and the resistance as a consequence so powerful, that in order to obtain the full benefits of the measure ether had best be given. A cotton tampon wet with glycerate of morphia, or other sedative, makes an appropriate dressing; rest in bed for a day or two, and in some cases even longer, is a most desirable precaution against cellulitis or other possible after-complications, and the hot vaginal douche, if properly used, may be made to play an important part in contributing to successful results.

Not every case of so-called spasmatic or neuraltic dysmenorrhea will be cured by dilatation—it were too much to claim infallibility for any method—but I am sure that I speak within the limits of truth when I asseverate that a large number of cases will be entirely relieved of all suffering at the menstrual epoch, that not a very large number will undergo such a modification of their sufferings as to be rendered comparatively comfortable, while only a small minority will fail of any sort of benefit thereby.

Now, be it remembered, I am speaking of the benefits of dilatation in a class of cases wherein it has heretofore been considered an unnecessary procedure, by reason of the already tolerable calibre of the cervical canal, and the apparently unobstructed outlet for the menstrual flow, as indicated by the ready passage of the probe or sound. I present a case, if you please, which is free from abnormalities of position, both as to kind and degree, one which at all events is free from the complications of dyspareunia, the metritis, as it is called, and shape, and in which the relations of cervix and body are natural; a case where the os and cervix uteri are patent if not patulous, without any observable mechanical opposition to the egress of the catamenial fluid; and yet, nevertheless, a case which is subject to all the agonizing sufferings of dysmenorrhoea in its more aggravated form. It shall be, or many, with which we are all so familiar, and which are even more painful to endure than the agony of the disease itself. I present a case, moreover, which has resisted all the usual remedies, internal and external, which are ordinarily employed, but which I need not now enumerate; medicines and methods whose efficacy and relative value we can all attest and appreciate, and which, withal, have been employed with conceded skill and judgment, and a persistency never so relentless.

Here, then, is the case where I should confidently expect good results from dilatation; for in such a case, I should be almost certain to find thickening and great hyperesthesia of the structures about the inner os. Reverting for a moment to the mechanical dilatation of the cervix, the consideration of the etiology of the case, we nevertheless have a somewhat analogous condition to that found by Dr. Otis in "strictures of larger calibre," and requiring a similar management for its relief. In a case like the one just described the tissues about the so-called os uteri internum, particularly those forming what I shall, for the sake of convenience, term its anterior lip, will, speaking generally, be found considerably thickened, even though there be no anteflexion, and this thickening will oftentimes extend downward along the anterior wall of the cervical canal in the shape of an inverted cone, the apex of which finally loses itself in the softer and more natural structures of the subjacent tissues of the cervix. This pyramidal-shaped body generally presents great resistance to the dilating instruments, becoming as it has of a hard and gristle-like formation, or presenting that sensation through the instrument to the operator whenever it is pressed upon with even moderate force. This leads me to remark, just here, that for such a case I prefer the use of one of the larger dilators, say that of the two-bladed expanding dilator; for the bougie makes pressure more directly upon the thickened and sensitive tissue, thereby more certainly relieving nerve-tension and more efficiently promoting absorption of the hypertrophic enlargement which seems to be the true seat of the nervous.

How, then, let us inquire, do the dilators act in removing the head and front of all this offending? Though aware that it is much easier to ask questions than to answer them properly, I venture, in reply, to offer the suggestion that they act in a two-fold way: First, by stretching out the nerve ends or filaments which have become entangled in the hypertrophic mass around the os internal, the sensibility becomes so blunt that they do not as readily take umbrage at the phenomena which occur during menstruation. The principle appears much the same as that in which nerve-stretching relieves ordinary neuralgias. Second, by pressure upon the thickened and hardened tissues partially surrounding the os, and extending downward along the cervical canal, they set up or promote absorption of the morbidly hypertrophied structures.

Can these results be expected to ensue from a single dilatation? Manifestly this is too much to hope for in every case, though it does doubt take place in a few; at all events, they are relieved of the symptoms for which advice was sought, and as this is the desideratum aimed at by any or all methods, it must, perchance be
accepted as prima facie evidence of cure. More often, however, repeated dilatations will be found necessary in order to realize the best benefit by the method; and I wish to lay considerable stress upon the assertion, based as it is upon the cases which I have personally observed, that consecutive dilatation offers the better probabilities as to permanency of cure.

To rid myself of any possible misapprehension regarding the method of employing dilatation which has been most successful in my hands, let me briefly formulate its more salient points as a conclusion to this paper, even though it involves a repetition of some of its parts.

Given a case of neurotic dysmenorrhea, occurring in either an unmarried or sterile woman, I should aim to make at least two appointments for the use of the dilators during each intermenstrual period, the last one to be not more than two or three days before menstruation. Commencing at each stage with such a bougie as will pass easily and without pain, one after another, of gradually increasing size, are introduced, until the limit of endurance on the part of the patient is reached, whereupon the dilator is allowed to remain in situ for ten or fifteen minutes. If sufficient stretching can be accomplished without causing discomfort, the treatment is considered good; but if not, then its employment is recommended.

By this process we not only overcome any spasmodic action which may lurk in the muscular fibres surrounding the internal uterine orifice, but, best of all, we bring that continuous pressure to bear upon the thickened cervical walls which exercises a most potent and material influence in expelling those cases of tenacious, even hemorrhagic, mucus and polypi. Having thus disposed of the usual factors predisposing to chronic invalidism in too many young women of the land.

February, 1884.

SOME REMARKS ON THE SUBJECT OF CLEFT PALATE.

BY A. VANDERVEER, M.D.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY ALBANY MEDICAL COLLEGE, ATTENDING SURGEON ALBANY HOSPITAL, CONSULTING SURGEON ST. PETER'S HOSPITAL.

Mr. President: It is my intention to follow this brief paper with a series of questions addressed to such surgeons as may be interested in looking into the deformities of the mouth, with a view to ascertaining, if possible, what percentage of cases are really benefited by the various operations as well as the success attending the use of mechanical contrivances. It is not improbable that but statistics may be of great value, either in placing the operation where I have reason to feel it belongs, or in the hands of some of our surgeons with whom I may be in leaving the cases entirely to themselves, to struggle on through life, perhaps to be treated only by our much-respected friends in the dental profession.

The subject of cleft of the hard and soft palate is one not so well settled in the minds of surgeons as to exclude further elucidation, and while it is hardly safe for one to attempt to advance such that I am now, I am convinced that more careful examinations and reports of our cases one, two, or more years after the operation has been performed are needed. It will ever remain a source of regret to the profession that such successful operators as Warren and Ferguson, the latter operating over three hundred times, did not leave a more correct record as to the results, the primary success, the difficult operation being the benefit resulting in the restoration of the speech, especially in pronunciation. I care not how the operation may have been done; and surely the writers upon this subject have been sufficiently numerous and clear to place the steps of the procedure in so plain a light that none need err in doing it.

In a clinical lecture of mine, found among the published volumes of "American Clinical Lectures," edited by Dr. E. C. Seguin, I have presented the different steps and manner in which I was to operate, the method being strictly that of Sir Wm. Ferguson, whom I had seen operate a number of times.

I have said a difficult operation, and such I consider it when the attempt is made to close a complete cleft. I have never yet been obliged to stop an operation because of hemorrhage, but I had it present at times to an alarming degree. Once I was obliged to postpone an operation because of the great and rapid secretion of mucus, it being so severe that the bronchi filled to a dangerous extent, and suffocation seemed imminent. In the second attempt I put the patient for a day upon the use of bella- donna with good effect. It is one of the few operations when done on children in which I regard chloroform safe. I never use chloroform in any other operation, and not in doing this after ten years of age. It is an operation where experience is of service as to dexterity, as to time consumed in doing it, and in teaching parent or nurse how to improve the speech afterward, and also, I believe, as to the time of selecting the case for operating. I believe that if we could get honest statistics we would find that the best time for operating is immediately after first den- tition, say when the child is about two years old, and that previous to this no attempt ought to be made toward having the child talk. Then there is not so much danger of acquiring that nasal twang which is so difficult for an older person to overcome. The cases of incomplete cleft, where there is no hare-lip, I would also include in this period.

I wish now to present in a practical manner the arrangement of cases, speaking almost entirely of the congenital form of cleft and as to the manner of operating, also as to the results in regard to speech, and to contrast the time at two years of age and when the operation is done later. In all cases of cleft I would operate upon the latter malformations first and at as early a date as possible. The union of the soft parts does aid, I am convinced, in bringing together the bony vault of the mouth, which is very desirable. Then, again, it does to a certain extent carry the child out from the domain of idle curiosity and contempt, and dare to speak with more assurance.

Some of these children will die before reaching the age of two years, not because of imperfect mastication, but they are bound to bear their ratio of death with the rest of the infant family. In double hare-lip, while the treatment of the intermaxillary bone has been dealt upon very clearly by the various writers, I am convinced that the different complications included with that experience is of the greatest service, and that almost every case presents one or more peculiar features, the same condition not to be seen again in a number of cases. To save it when possible is, I believe, good surgery. There can be no doubt but that it preserves the fulness of face and in after years prevents the childlike contraction or appearance which is so striking in some adult faces. I think the cases are few where in saving the island you can go on and unite both sides during the same operation.

As to the manner of closing the single hare-lip there need be little difference of opinion. The law is inflexible that to procure a good result the vermilion border of the lip must be always on a line, projecting if possible a little. If not, an apparent notching occurs.

Regarding the manner of dealing with this island, as my experience goes, I wish to present the following cases, having this in mind, that if I cannot save the bone I try to save the healthy skin covering it, be it ever so small, and to shape it in such a way that by angle, curve, or combination I fit it either into, between or above to one side of the upper lip, using the latter as flaps—the small portion aiding in its way to prevent the contracted appearance of the face.

In the following case, sent me by Professor Bigelow, of
THE MEDICAL RECORD.  

[February 9, 1884.

this city, there presented that dreadful deformity, such as is seen in a minority of cases only, for which we should be grateful, with the island shooting up almost like a horn toward the nose. There was covering it quite a surface of healthy skin and I determined to save all. Accordingly I first took from the septum, with curved bone forceps, a V-shaped portion of bone, and then broke the island into position on a level with the alveolar ridge of the upper jaw and held it there for a period of ten days with compress and adhesive plaster.

Two weeks later I freshened the edge of fissure on right side, also edge of skin covering the island, and then brought the flaps up on that side up to it, holding it there with two silver pins, and got good union.

Two months later, and when the child was not quite six months old, I treated the fissure on the left side in a similar manner and got a perfect result. Unfortunately, in the sense of completing the operation for closure of cleft in the hard palate, this child died of cholera infantum just at the end of its second year, and at a time when its parents were ready and anxious for the final operation.

The saving of the island I am sure gives a better septum for the nose, as is reasonable to conclude when comparing this case with another in which the island was removed.

Master B——, aged six months, had a double hare-lip with the intermaxillary bone so prominent that it was deemed best to remove it entirely. This was done in the first operation, lateral incision made from angle of nose on each side outward to the cheek and then the two flaps formed the upper lip were brought together, the child being quite perfect for the purpose, and in the same year, two operations were required for closing the cleft in hard and soft palate, but his voice did not improve as I had hoped. I did not see him for nearly three years, when he was brought to me and on examination I found the upper lip had no union with the septum or vomer, and that through this opening the air escaped in such a volume as to partially account for the non-success in speech. These cases are difficult to remedy, and while in this case I advised further operative interference, the parents, who live some distance in the country, have not presented the little fellow.

Master C——, aged four years, presented through the kindness of Dr. Fisher, of Worcester, N. Y., made a most frightful appearance at the first examination. We operated on him the same number of times, saving the intermaxillary bone, with a result as to appearance and voice nearly perfect.

As to results in closing cleft of the hard and soft palate, after watching the patients for several years, if I never operate again, I shall feel all my hard work has been well rewarded in the restoration of speech, as seen in the cases following.

Lizzie C——, four years of age, with a complete fissure of the soft palate and cleft of the hard, was operated upon, June 9, 1874, by the periosteal operation of sliding the soft tissues unsuccessfully. A year later I did Fergusons operation with the most gratifying results, the child being able to talk, sing, and use her voice as well as other children. At the present time it would not be suspected that she had ever suffered from any deformity of the mouth.

Eddie M——, three years and four months of age, born with complete cleft hard and soft palate, was operated on in same manner as little girl; first, Fergusons operation being done February 3, 1876, followed by two others before the cleft was entirely closed. He is now in possession of as perfect speech as one could wish, being understood by his playmates, and while in school there is no noticeable difference in his tone of voice.

A patient, Miss T——, was operated upon June, 1880, by the simple severance of nostril, which had succeeded only fairly in doing the periosteal flap operation. I did the full Ferguson, getting almost complete union, yet was much annoyed afterward in three distinct attempts by cautery and operation before getting entire closure. She has never been able to throw off completely the nasal tone, an evidence, I am convinced, that the operation ought to be done early and time has almost overcome the twang.

A bright contrast is seen in the case of Master F——, seven years of age, who was operated upon, February 16, 1880, for congenital cleft of soft palate, attended with a condition of enlarged tonsils rendering his speech nasal and very indistinct. The edges of the blind uvula were pared; four sutures were introduced, one of which was passed directly through the velum; a small buttonhole was incised at the hamular process to relieve the tension, with the result, one year after operation, perfect in every respect. That the operation is a severe, and I might say difficult one, there can be no doubt. That repeated failures in closing these cases caused some caution on my part, I am willing to admit, yet in these cases, one or two exceptions, I have finally conquered, and in neither was the patient left any the worse for the future trying of an obturator.

These cases do get on in life without any operation being done and are then improved by use of obturators. I am sure that it is simply a question of time and temperament. When eighteen years of age, by the use of obturators. Has never been in the least improved, and life has been to him a sorrow. It is with great difficulty he can be understood.

The cases are not always so benefited. Mr. S——, aged seventy, was operated upon when a child for hare-lip, by Guthrie, and then given to the dentists for relief, when eighteen years of age, by the use of obturators. Has never been in the least improved, and life has been to him a sorrow. It is with great difficulty he can be understood.

The case of Master F——, required no less than five operations, the first done for hare-lip at six weeks of age, and the others for cleft palate later, beginning when he was two and a half years old. Yet, were you to see him now, I am sure you would exclalm with his faithful aunt, "All trouble and care have been fully rewarded; his speech is almost perfect."

FOR HEMORRHOIDS.—Dr. Benj. Lee, of Philadelphia, recommends the following (Medical Times):

B. Pulv. rhei. 3 iv. Pulv. aloes. 3 ij.
Pulv. myrrh. 3 ij. Sapon. hisp. 3 iss.
Ol. cajeput. 3 j.

The powders are to be rubbed together and the soap then worked in, afterward the oil. The well-mixed mass is kept in tight bottles. The freshness it is the better. Three grains of this mass make an effective pill, which is non-irritating, and may be used a long while without diminishing the susceptibility of the intestines, and often with positive benefit to the hemorrhoidal affection. Cascara sagrada in two-grain doses is also beneficial.
Progress of Medical Science.

MENTHOL AS AN ANODYNE.—Dr. E. C. Wendt, at the last meeting of the Neurological Society, showed a little contrivance, called by the Germans "migränestifft," and explained the method of its application and uses. It consisted of a piece of menthol moulded into a conical shape, and secured in a little wooden box, closed by a cover to prevent evaporation, soiling, and breaking. It seemed to be very little known here, although it was much used abroad, especially for sick headache.

His attention had been first directed to the anodyne properties of menthol by a short notice, published in The Medical Record of April 28, 1883, by Dr. Cammann. That gentleman had recommended an alcoholic solution of menthol (3 J. to 2 oz. alcohol) to be painted over the affected parts. Dr. Wendt had, since that time, often used this solution, and found it a rather reliable anodyne. Its pain-relieving action was restricted, however, to the slightest ailments, especially those of a neuralgic character. Since his acquaintance with the solid menthol-cone, he had frequently substituted the direct application of menthol by means of the latter for the solution formerly employed. He would admit that the only advantage which the solid cone or pencil had over the solution consisted in the greater simplicity of its application, its ready portability, and the fact that its vapor was not apt to irritate the eyes of susceptible patients. He had repeatedly heard complaints in that direction from ladies regarding a solution, which "burns" when using the cone.

In this country menthol had not yet received that amount of recognition from the profession to which its pain-obtunding properties would seem to entitle it. Dr. Wendt here quoted from a descriptive notice, which had appeared in the Midland Medical Miscellany of October, 1883: "Menthol, or menthylic alcohol, is a crystalline substance deposited from the oil of peppermint, prepared in China and Japan from mentha arvensis var. pipericas and glabrata."

It formed the chief ingredient of a much-valued remedy for neuralgia before its nature or source was generally known. Under the name of po-ho-yo, or gouttes japonaises, it is sold in small bottles in China and Japan, in bottles written with Chinese characters. It is a white crystalline stearoptine, melting when pure at 97° Fahrenheit, and is obtained by the Japanese from the oil of peppermint by submitting it to freezing several times in succession until no more menthol crystallizes out. It is also said to be contained in the American and English oils of peppermint, but probably in small quantities only. The supply of menthol is uncertain, the demand great, and the price, in consequence, occasionally very high.

Menthol is said to be sometimes adulterated with crystals of Epsom salt, to which it bears a great resemblance. These being insoluble in alcohol or chloroform, in which a fluid menthol is freely soluble, can easily be detected. Samples of fine crystals sometimes contain some essential oil adhering to them, a fact which must be taken into consideration when the menthol is made into cones or pencils."

Menthol is but slightly soluble in water, although imparting a strong odor and taste to that liquid, and is soluble in aqueous alcohols. It is soluble in fixed and volatile oils, and in ether.

Although Dr. Wendt's experience with menthol had not yet been a very extended one, it had nevertheless been sufficient to convince him of the utility of the drug in a rather large class of cases. Thus, as already stated, he had found it a pleasant and reliable anodyne in all those cases, and especially in those so frequently occurring about the face. But it was also serviceable in many painful affections due to inflammatory processes. For example, in mumps, in the cervical adenitis so often accompanying sore throat, and in numerous other affections where pain was a prominent symptom, menthol might be used to advantage. With regard to its topical action, it was subjected to that influence over which it had the advantage of not being poisonous.

Dr. Wendt related one rather striking case of quite severe supra-orbital neuralgia, which refused to yield to the oleate of aconitum, but was much benefited by the menthol. But on the whole, in violent attacks he found it almost useless. In typical migraine, for instance, where the pain was at a severe point, and in wounds caused by the force of more than very moderate intensity, it had no appreciable effect, except, perhaps, the indirect psychical action of distracting the sufferer's attention.

TURPENTINE-IODOFORM.—A solution of iodoform in turpentine is lauded by De Renzi (L'Imparsiale, November, 1883), as quite beneficial in pulmonary troubles, more especially, however, in phthisis. Five drops of the solution are to be poured on wadding and then inhaled. This is to be repeated every few hours. The method is not entirely new, but does not appear to be much used in our country.

THE EFFECTS OF A WARM FOOT-BATH.—In order to determine whether the warm foot-baths were of any value as a derivative in cerebral congestion or as a means of inducing a congestion of the pelvic organs, Dr. Sciol- cowsky made a number of observations, noting the changes of temperature in the external auditory meatus, the axilla, and the rectum. The duration of each foot-bath was from fifteen to twenty minutes, and the temperature of the water was from 93° to 97°. He found that the temperature rose in the axilla and external auditory meatus, while it fell in the rectum. The volume of the vessels in the upper extremities was decreased. There was an increase in the frequency of the pulse and in the blood pressure. These observations showed that the warm foot-bath diminishes the flow of blood to the abdominal and pelvic organs, while at the same time there is an increased flow to the superficial parts. The foot-bath, then, neither diminishes the hyperemia of the brain and its envelopes nor increases that of the pelvic organs.

Memorabilia, No. 7, 1883.

PROPHYLACTIC TRACHEOTOMY IN A CASE OF TRAUMATIC EMPHYSEMA OF THE HEAD AND NECK.—Dr. H. Schmidt relates the case of a man who struck his neck against a pole. In a few hours an emphysema was developed, extending on the right side to the third rib. The voice became hoarse. Owing to the rapid development of the emphysema, and the fact, as shown by the changed voice, that it extended also beneath the mucous membrane in the neighborhood of the larynx, Dr. Schmidt determined to perform tracheotomy. This was done with immediate relief to the respiration, which had been difficult. No more trouble was experienced, the emphysema rapidly disappeared, and after twelve days the canula was removed and the patient allowed to resume his work. The voice, however, was permanently changed.—Memorabilia, No. 7, 1883.

POISONING FROM A LEECH-BITE.—Dr. Gmeiner relates a case of fatal poisoning from a leech-bite, occurring at Bern (Journal de Médecine de Bruxelles, vol. lxvii., 1883). A man who was suffering from severe toothache, on the advice of a dentist, applied a leech to the gums. After a couple of hours the pains increased and a slight inflammatory redness appeared on the lips, soon spreading over the neck and chest. The following day there was swelling of the tissues about the head and face, and the patient had a high fever and dyspnoea. A few hours later he became delirious, had convulsions, and died the following night. The leech was of some size and black in color. The leech had been for a considerable time in the pharmacy where it was procured, and it was impossible to determine the nature of the poison from which the man died.
THE MEETING OF THE STATE SOCIETY.

The meeting of the Medical Society of the State of New York, which for several reasons was looked to with interest by the profession throughout the country, was, as might have been anticipated, largely attended.

The scientific work was up to the ordinary standard, and would have been above it except for the lack of opportunity for the presentation of many papers in waiting. There is shown more and more a disposition on the part of members from the State to contribute to the scientific proceedings by practical articles. As an earnest of what is appreciated we are pleased to see with what favor papers from the general practitioner are received, and what interest is awakened and discussion is stimulated by contributions bearing upon the treatment of the commoner diseases. Specialism occasionally spices the feast with a brilliant suggestion, but the solid every-day food for the general worker must be gathered from the ordinary experience of the masses. Hence we note, in passing, how easy it was to start an instructive discussion upon the much-used and much-abused chlorate of potash as a gargle. If there was anything deserving criticism regarding scientific discussions it was that there was too much hurry in the transaction of the great mass of business to allow the proper opportunities for the free interchange of views. Still it was perhaps the best that could be done under the circumstances.

The Code question came up for discussion as a matter of course. Every member and delegate was prepared for the issue. The discussion was a necessary preliminary to the voting. In the former nothing new was presented in the way of argument pro or con. Indeed, it would be difficult to understand how it could be otherwise, in view of all that has been said and written upon the subject. Hence it is fair to assume that the minds of the members were made up, and that discussion did not secure a change of vote one way or the other. The gentlemen advocating a return to the Old Code came out in force, and their arguments received the respectful attention of the audience. It is to be deplored, however, that the general good temper of the discussion was marred by a threat by the Old Code advocates to secede from the Society in case the majority was against them. On general principles there was no excuse for this. However much many members of the profession may sympathize with them in their views, they will not overlook the bad policy of resorting to such a device. But this point hardly needs discussion from any reasonable standpoint. The advocates of the New Code again win, and the result as given by the ayes and nays is acknowledged by all to fairly represent the views of the State Society on the question at issue.

The subject of State examinations very properly received full consideration. It is quite apparent that the Society, in common with the profession at large, is in favor of such examinations. Even the colleges are forced to acknowledge the necessity of the measure. Public sentiment is too strong the other way to leave any doubt on this score. It was only regarding matters of detail on which any radical differences of opinion rested. Hence it was eminently wise, in view of the importance of the proposed bill, to defer definite action upon it until next year. In the meanwhile, the more the profession and the public know about the subject the more firmly will they be convinced of the necessity of separating the teaching and licensing powers in our medical colleges. Years ago The Record advocated State examinations, and it is firmer than ever in the belief that they are imperatively demanded by every one not directly interested in the so-called prosperity of the colleges. The time must come when State examinations will be enforced in New York, as elsewhere, and until then we shall strive to be consistently earnest in the advocacy of the measure.

THE DISPENSARY QUESTION ABROAD.

Misery, it has been said, loves company. But even if our uncharitableness does not extend to the limit of an unqualified acceptance of this dictum, we may yet find some slight consolation in our troubles by regarding those of our neighbors. It may then be brought home to us that there are people who have still greater ills to bear than we. While not actually rejoicing in their misery, we may nevertheless feel thankful that ours is not as great as it might be. Viewed in this light, it seems almost perniciously pleasant to learn that the dispensary and college evils exist in other lands as well as in our own.

In a letter to the editor of Le Médecin Praticien, a physician of Paris bewails the condition of the majority of his confrères in that city. One-tenth of the population of Paris, comprising the nobility and the people of large fortunes, is reserved, he says, for the college professors, the great specialists, and those holding hospital appointments. Another tenth, in which are the small shopkeepers and more honest bourgeois, employs the mass of the profession, paying their bills at the end of the year, except in case of a political or financial panic, when their memories grow treacherous, and they simply refuse to remember anything about them. The average fee for one call among this class is three francs, or sixty cents. The remaining eight-tenths of the populace are provided for by the hospitals, dispensaries, and public clinics. One-tenth of the physicians is supported by the wealthy tenth of the population, while the remaining nine-tenths of the profession live miserably on what the other tenth of the population, comprising the more honest portion of the middle class, condescend to pay them.

Some of the causes of these evils he finds in an excessive number of free hospitals and dispensaries, in which
relief is given indiscriminately to all who apply. But there are also too many Facultés de médecine, and too many doctors. The remedies suggested are, among others, the exacting of proof from those applying for gratuitous medical relief that they are really deserving of charity, the abolition of some of the medical schools, and the refusal to foreigners of the right to practise without first passing an examination in France. "Create fewer, but better-educated doctors," he exclaims, "and assure to them, after the great expense incurred and labor expended in obtaining the needed education, an honorable position, worthy of so great a nation as the French." Truly, the condition of practice in Paris seems to be very like that in New York.

Similar complaints are heard in Vienna. An editorial appeared not long ago in the Allgemeine Wiener Medicinische Zeitung, entitled, "Ought Poor Men's Sons to study Medicine?" The question had been raised by a correspondent of another journal, who asserted that the expense of a medical education in Vienna had become so great that none but the rich could meet it. The editorial writer very properly maintains that it is bad surgery to amputate the foot because of a tight shoe, and if the cost of a medical education is so great that a young man of moderate means cannot meet it, the State should undertake to pay the professors and not allow them to take fees from the students. But the trouble, he says, lies less in the cost of procuring an education than in the precariousness of the livelihood of a young physician after his right to practise is granted. The cause of this he finds in the great number of "charitable, or rather patient-grabbing institutions, policlinics, and dispensaries." The same old story! The writer quite hopefully concludes that, sooner or later, there must be a change. All these evils will right themselves in time. We hope as much also.

THE CONTAGIOUSNESS OF PHthisis.

One of the evil results of the recent discoveries concerning the nature of tuberculosis has been the strengthening of previously only vaguely entertained suspicions of the contagiousness of phthisis. Since it has been conclusively shown that, with tuberculosis, there is found associated a micro-organism, many have rushed to the rash conclusion that it must of necessity be contagious. Others have even gone so far as to insist upon the strict isolation of all consumptives. But while it is true that the disease may, under certain circumstances, be communicated from the sick to those about them, every day experience teaches us that such occurrences are exceptional, and certainly far too rare to justify the cruelty of excluding such poor sufferers from grateful companionship with their fellow-creatures.

It is quite pertinent to refer here to the work done by the Collective Investigation Committee. Concerning it the British Medical Journal says: "A large amount of impressive evidence is forthcoming, that persons who are free from hereditary predisposition may acquire phthisis by being brought into very close personal contact, and especially from sleeping with phthisical patients; but the precise conditions under which the disease is communicated have yet to be studied. While this is perfectly true, it must also be remembered that communication is rather the exception than the rule, and that, while it suggests the precautions of good ventilation, disinfection of air and spuits, and separate beds, sufferers from this disease may be tended with comparatively little risk."

It may also be of interest in this connection to allude briefly to the results of some experiments recently undertaken by Drs. Celli and Guarneri, and published in the Gazeta degli Ospitali, No. 56, 1883. These investigators were unable, after the most careful search, to find tubercle bacilli in the air of an unventilated room in which phthisical patients had been sleeping. The expired breath of these patients was likewise found to be entirely free from bacterial contamination. Nor could the specific micro-organisms be discovered in air which had been passed through the spuits of tuberculous patients, although in every case the expectorations were found to contain them in large numbers. They were also unsuccessful in attempts at inoculation with fluids impregnated with this presumably vitiated atmosphere. It would thus appear that the fears of those who lay too much stress on a priori reasoning and too little on the facts of common experience, are to be treated as an exaggeration of morbid apprehensiveness.

News of the Week.

THE FIRST CLINICAL LABORATORY IN SWEDEN was recently opened at the Upsala University.

AN AWAKENED CITY.—We are very glad to see that our fraternal and admiring neighbor, the city of Philadelphia, is arousing itself into renewed activity of late. Two new medical societies have recently been, or are about to be organized, viz., a neurological society and a medico-legal society. If brotherly love continues after this among the profession of Philadelphia, we shall make our obeisance and try to negotiate an exchange of site between the New York and Philadelphia societies.

"THE ANALYCTIC" is the title of a new monthly journal published by G. P. Putnam's Sons, and edited by Dr. Walter S. Wells. It is devoted to giving a summary of progress in the various departments of medicine and surgery. The selections in the first number show that the editor has an excellent idea of the needs of the general practitioner. The journal is very well printed, and is placed at a moderate price.

OUR UNIQUE AND LUMINOUS CONTEMPORARY, The Planet, has unfolded the Old Code flag, and is making original reports of the city medical societies. It is pressing The Record hard.

A TRAINING SCHOOL FOR NURSES is well under way in St. Louis.

A BILL FOR THE REGULATION OF PHARMACY and the examination and licensing of all pharmacists by a State Board is now before the Ohio Legislature.

THE ST LOUIS COLLEGE OF PHYSICIANS AND SURGEONS.—We have received from Dr. Wm. B. Hazard, Secretary of the Board of Trustees of the above institution, a letter denying as "false and slanderous" the statement which we published to the effect that there
was dissatisfaction and rebellion in the college. According to the Weekly Medical Review, the statements which we quoted are essentially correct, i.e., eight members of the faculty have sent in their resignations, but these have not been accepted, and the lectures are continued for the present; the students also have pledged themselves to support the eight resigning professors, but continue their attendance at lectures for the present. We have no desire to do other than represent the truth, which we believe has now been done.

Dr. Stickler’s Article.—In the article “Subnormal Temperature in Certain Malarial Affections,” in Medical Record of January 26, 1884, read pulse 84, instead of 18, in note for September 8th of Case I. Period instead of comma after temperature, in fourth line of introduction.

Medical Bills at Albany.—A bill has been introduced into the Assembly amending the charter of the College of Pharmacy of the City of New York, by allowing it to receive bequests to the extent of $300,000, and to confer the degree of “Master in Pharmacy” as a higher distinction than “Graduate of Pharmacy.”

Physiology, Hygiene, and Alcohol in the Public Schools.—Senator Gilbert’s bill requiring instruction to be given in the public schools of the State on the subject of physiology and hygiene, with special reference to the effects of alcohol on the human system, occupied most of the session of the Senate last Tuesday. One of the opponents of the bill offered an amendment providing that a “fearful example” should be hired for each school at $1,000 per annum. The bill in its present form exacts too much and is a foolish one. Some temperance and hygienic ideas, however, might well be instilled into the young.

Cigar-Making in Tenement-Houses.—The Court of Appeals has decided that the law forbidding the manufacture of cigars in tenement-houses in New York City is unconstitutional. The decision was based, however, upon a defect in the title. The law in question was passed by the Legislature of last year, and went into operation on October 1st. Its passage was secured largely by the influence of the trades unions, who claimed that the effect of making cigars in tenement-houses was to cheapen the price of labor. At the time when the law went into effect there were 127 apartment-houses in the city where cigars were made, and 1,964 persons, consisting of 7,924 persons, were engaged in this industry.

The Philadelphia Neurological Society has been organized with the following officers: President—Dr. S. Weir Mitchell; Vice-Presidents—Drs. Charles K. Mills and Isaac N. Kerlin; Secretary and Treasurer—Dr. James Hendrie Lloyd.

Virchow on American Pork.—Professor Virchow has recently come out in favor of the American swine. He declares that there is no danger in it—that the sifting it out from Germany is a political, not a sanitary measure.

A New Medical College at Quincy, Ill., is announced. There are still several cities in the United States having as many as thirty thousand inhabitants yet without a medical college.

The Sims Memorial Fund.

To the Medical Profession and Others throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting testimonial than obituary or eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations, and such as have had the direct advantage of his personal skill are among the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulse to the study of gynecological surgery in America.

It is believed that the medical profession everywhere, the vast number of women who owe their relief from suffering directly to him, and those who realize the benefits he first made possible, will gladly unite thus to honor the man through whose original and inventive genius such blessings have been conferred upon humanity.

At the suggestion of many friends, therefore, the subjoined committee has been organized, and it is proposed that a suitable monument be erected to his memory in the city of New York.

To this end the active co-operation of the medical profession and the many other friends of Dr. Sims throughout the world is respectfully solicited. Contributions of one dollar and upward may be forwarded to the journal which has been constituted the treasury of this fund—The Medical Record, New York.

FORDYCE BARKER, M.D., Chairman.
GEORGE F. SHRADY, M.D., Secretary.

THOMAS ADDIS EMMET, M.D., New York.
T. GAUILLARD THOMAS, M.D.,
WILLIAM T. LUSK, M.D.,
WILLIAM M. POLL, M.D.,
PAUL F. MUNDE, M.D.,
S. O. VANDER POLE, M.D.,
FRANK P. FOSTER, M.D.,
E. S. GAUILLARD, M.D.,
ALEX. J. C. SKENE, M.D., Brooklyn, N. Y.
WILLIAM GOODELL, M.D.,
JAMES R. CHADWICK, M.D., Boston, Mass.
WILLIAM H. BYFORD, M.D., Chicago, Ill.
A. RAFFES JACOBS, M.D.,
THAD. A. REAMY, M.D., Cincinnati, O.
C. D. PALMER, M.D.,
GEORGE J. ENGELMANN, M.D., St. Louis, Mo.
R. BEVERLEY COLE, M.D., San Francisco, Cal.
H. F. CAMPBELL, M.D., Augusta, Ga.
R. B. MAURY, M.D., Memphis, Tenn.
E. S. LEWIS, M.D., New Orleans, La.

A. W. KNOX, M.D., Raleigh, N.C.
L. W. OAKLEY, M.D., Elizabeth, N. J.
E. A. WOODWARD, M.D., Brandon, Vt.
ALFRED CROSBY, M.D., Concord, N. H.
H. E. DUNSTERT, M.D., Ann Arbor, Mich.
ALEX. J. STONE, St. Paul, Minn.

Other names may be added to this list from time to time.

The list of additional subscribers to the Sims fund being unavoidably crowded out of this number will appear in our next.
MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Seventy-eighth Annual Meeting, held in Albany, Feb-
uary 5, 6, and 7, 1884.

TUESDAY, FIRST DAY—MORNING SESSION.

The Society convened at Geological Hall, and was
called to order at 10 a.m. by the President, ALEXANDER
HUTCHINS, M.D., of Brooklyn.

Prayer was offered by the REV. DR. KING.

The President then delivered his
INAUGURAL ADDRESS.

He began by suggesting some reforms in the methods
of society work. At present only about eight hours out of
the three days could be devoted to scientific work. He
advised the adoption of some authoritative method
of securing papers, and suggested the announcing at each
meeting of queries to be answered next meeting, and of
having an "omnibus meeting," wherein individual expe-
riences are freely and briefly discussed. The work of
the State Board of Health was dwelt upon and com-
mented. The State Board has twelve hundred local sanii-
tary boards. He advised the formation of a committee
to urge the passage of the House Bill (H. R. 48), pro-
viding for the erection of a fire-proof building for the use
of the Army Medical Museum and Library.

The President called attention to the subject of hospi-
tal trained nurses as an advance in exact medical meth-
ods now being adopted in large proportions. He suggested the
advisability of making an appropriation for the support of
the Index Medicus. He referred to and deprecated a prac-
tice, which has been growing, of county societies ad-
mitting to active membership physicians who resided in
neighboring counties, and who were members of other
county societies. He urged that the Society undertake
the publication of an authoritative register of legally qua-
lified practitioners in the State. He suggested that the
Censors in the different districts, who have yearly the
privilege of appointing a beneficiary student to one or more of the medical colleges of the State, be
advised to report to the Society whom they recommend.

The President then took up the subject of medical edu-
cation, particularly in the matter of the laboratories. He
acknowledged the evils that now exist and referred to
the proposed medical bill, which provided for the taking
from the colleges the power of licensing. He advised
great caution in endorsing so radical a measure.

The relation of the State Society to the county socie-
ties was discussed at length. It was a statutory pro-
vision that the county societies make their by-laws con-
form to those of the State Society, yet this had been
done by only sixteen county societies.

The subject of the action of the Society with reference
to the codes was taken up. The State Society he said
now contains 193 delegates and 256 permanent members.
The latter, therefore, can legitimately control the action
of the Society, and their presence gives to it more of an
autonomy, and makes it less of a purely representative
body. The Society has it in its power, therefore, to
adopt a position not in harmony with the feelings of the
majority of the profession. This it can legitimately do.

A list of members who had died during the past year
was read and appropriate remarks made.

The President then appointed the following Com-
mitttees.

Business Committee—J. W. Moore, of Cohoes, Albany
Co.; A. M. Phelps, of Chateaugay, Franklin Co.; J. H.
Hunt, of Brooklyn, Kings Co.

Committee on Credentials—J. N. Goff, of Cazenovia,
Madison Co.; James Chapman, of Medina, Orleans Co.;
P. R. H. Sawyer, of Bedford, Westchester Co.

The Society then took a recess for the purpose of al-
lowing members to register.

On reassembling, communications from
COUNTY SOCIETIES
were called for and the following were presented and
referred.

A communication from Albany County endorsing the
Bill of the Committee on Legislation of the State Medical
Society with reference to a State Board of Medical Ex-
aminers. On motion by Dr. Piffard it was made a special
order for Wednesday morning, immediately after reading
of the minutes.

A communication from the Medical Society of the
County of New York, containing certain amendments to
its by-laws. Referred to the Committee on By-Laws.

A biographical sketch of James Lenox Banks, M.D.,
of New York, by Dr. F. A. Burrall, of New York, was
presented and referred to the Committee on Publication.

DR. WESLEY M. CARPENTER read a
BIOGRAHICAL SKETCH OF J. MARION SIMS, M.D., LL.D.

On the 25th day of January, 1813, in Lancaster Dis-
trict, South Carolina, a man child was born. Only a
brief account of his boyhood days has been recorded, and
the history seems to be complete with the statements
"that he was a good boy, but a dull one at school" (Emmet);
"that he was an effeminate and gentle school-
boy of ordinary capacity, who elicited simply the love of
his fellow-students" (Kinloch), and "that in his classes
at school he stood fairly well, but was not precocious,
and attracted no particular attention beyond his hand-
somely chiselled face, his delicate physique, and his ge-

dial and playful turn of mind" (Baldwin).

The first of these quotations is an autobiographical re-
mark, and was supplemented, when read, with the comment,
"he may have been wanting in application, but if the
man was any indication of the boy, there could have
been no time of his life when he could have been dull
in any sense of the term" (Emmet).

From all that has been gathered, however, there is
nothing to lead us to conclude that he was markedly
different from the other boys with whom he associated,
unless it be included in the clause quoted from the eulo-
gist of his native State, "elicited simply the love of his
fellow-students."

This lad passed through the ordinary vicissitudes of
boyhood and early youth, experiencing pleasure and dis-
appointment as did his comrades, engaged in the usual
occupations and studies of his day, and as he merged
into manhood we find him a graduate (in 1832) with
the degree of Bachelor of Arts from the College of South
Carolina, at Columbia. During this period of prepara-
tory study we do not learn that he was distinguished
either as a writer or a debater, or that he was acknowl-
edged superior in general acquirements. The historian
tells us that soon after receiving his college degree he
became enamored with medicine, the study of which he
began in the office of Dr. B. C. Jones, then a leading
practitioner in his locality. He graduated from Jeffe-
son Medical College, Philadelphia, in 1835. But little
has been recorded of him as a medical student, and that
little has been derived chiefly from autobiographical reci-
tations and sketches. These show that he was a diligent,
enthusiastic student, and that he entered upon his pro-
fessional career with the average amount of medical
education.

His experience at the outset was an epitome of that
obtained by the young practitioner of medici-
ne, and his first case was graphically and humorously
described by himself in an address delivered at the open-
ing of the New York Post-Graduate School of Medicine,
in 1887. The case was one of cholera infantum, of which
he had heard but little and concerning which he knew
less than he had heard, but which he attended with pro-
found solicitude and resorted to all the known resources
for arresting the progress of the fatal disease. The history of the case terminated with the announcement made by the good old lady who had acted as nurse, and who, with her hands upon her hips and her elbows akimbo, looked straight at the young doctor through her spectacles and said to him as much as you please, but its dead." The young doctor thinking that the child had fainted, had laid it across his lap with its head hanging low, and was shaking it with the hope of reviving it by sending blood to the brain.

But nothing daunted, the young practitioner kept at work, and between the years 1840 and 1845, it has been recorded of him that he had a surgical practice which was one of the largest in his native State.

The circumstance which was utilized by the genius of the man, and which laid the corner-stone of his worldwide reputation, occurred in July, 1845. No memoir or biographical sketch will be complete without its recital.

"In July, 1845, he was called to a patient who had been thrown from a carriage and was suffering from a retroversion in consequence of the accident. During his effort to restore the uterus he placed her in what is now known as the 'knee and chest position'; but, finding that he could not fully reach the womb with the index-finger alone, he introduced the second one, with the immediate effect that he could then neither touch the cervix nor the walls of the vagina, and, to his surprise, she announced that she was entirely relieved. To this accident, and to the dilatation of the vagina when placed in a certain position after retracting the perineum with the fingers, we are indebted for the speculum bearing his name, and for the first operation by him in a case of vesico-vaginal fistula" (Dr. Emmet's Memoir).

"He was obliged to seek recuperation in a change of climate, and he migrated to New York, where we next find his name especially identified with the operation for vesico-vaginal fistula, and with the institution with which he was so honorably connected for many years. There has been some diversity of statement concerning the earliest history of the Woman's Hospital of the State of New York, but the central figure around which all others cluster was that of the subject of this memoir. Concerning its success and the relation which he sustained to it no comment is necessary on this occasion. Its influence for good will remain a more lasting monument to his memory than either branch or root.

An analysis of the characteristics of this distinguished surgeon reveals to us two striking features. First, he was neither satisfied nor inflamed with his successes; second, he was neither daunted nor discouraged by his failures. The first gathered about him a long line of faithful friends, for he greeted with ease, dignity, and affability the humblest, as well as the most eminent of his professional brethren, or patients; the second secured for him the faith which inspires hope; and both, sustained by his striking qualities as a surgeon, elevated him to the loftiest pinnacle in the midst of his peers.

It is not necessary in this place to refer in detail to the work which he accomplished. This has already been done by competent writers, and is fresh in the memory of every man who works in the same department in which he labored so brilliantly and so successfully.

"He was by nature a surgeon, and one of the most dexterous of operators. He was bold and self-reliant, never at a loss, and his ingenuity was unequalled. He was a skilled and clever operator, for his hands and body were always too restless and active. He was so fertile in resource that he perfected scarcely a tithe of the brilliant conceptions passing constantly through his mind, and it was impossible to see him perform the most simple operation without learning something new" (Emmet).

As a writer he was easy, terse, comprehensive, and at times ornate. Many of those who may read this biographical sketch will remember when he addressed this Society for the last time. He then presented the healthful vigor of youth in advancing years, and his contribution on "Thomas Keith and Òvariotomy" amply illustrates the above-mentioned qualities of his literary accomplishments. The ease with which he described the details of a protracted and delicate operation, and the comprehensiveness of the description is one of the most, if not the most, complete contribution which has ever graced the transactions of this Society, and may be followed as a most complete pattern by all medical writers.

Warming with his subject, he closed his paper with a pen picture of Mr. Keith, which, for simplicity, faithfulness of description, and elegance of diction, has not been surpassed. So marvellously complete and faithful was it that, when the writer of this sketch visited Edinburgh in the following summer, he said to himself, "There is Thomas Keith," as a carriage passed him and stopped on the opposite side of St. George's Square. A gentleman alighted before the horse had scarcely come to a standstill, and skipped across the walk and up to the door. So fully convinced was I that the impression was correct that I lingered about the public square until this gentleman came from the house, and again passed me on his way to his office, only two or three blocks distant, where I soon had the pleasure of looking into those "deep brown eyes, full of benevolence and gentleness," and of hearing "what is one of the most attractive gifts of nature, whether to man or woman, a sweet, musical voice."

"Thomas Keith is fifty-two years old, six feet high, slender, and slightly stoop-shouldered. He wears a full brown beard, and his fine large head is covered with a profusion of long, silky, golden, auburn hair, which hangs down behind, gently curling over his clasped collar. His forehead is broad and prominent, his nose is long and straight, slightly aquiline, beautifully symmetrical, and strongly indicative of character. He has large deep blue eyes, full of benevolence and gentleness; and he has what is one of the most attractive gifts of nature, whether to man or woman, a sweet, musical voice. He is as modest as a woman, and in character altogether lovely. He is quick in action, walks rapidly, as if he was trying to catch up with his great head, which is always in advance of his slender body. As he descends from his carriage he hurries across the sidewalk and runs up the steps, and has the door open before any of his horses or their groom can overtake him. He has a habit of intonation that his mind is always intense on the object of its pursuit, and he hastens to accomplish it. His whole soul is wrapped up in his work, and after he has performed a difficult operation he eats and sleeps but little till he knows that his patient is out of danger. I only wonder how a man of such high-strung, delicate, nervous organization could so long have borne up under the great and anxious work that he has done."

Why marvel that he who could command such beautiful and expressive words, so charming, so refined, and so full of glowing eulogy, should gain favor with the rich as well as with the poor, with the learned as well as with the ignorant, with the exalted as well as with the humble, and that his name should be so dear to so many that for years to come the memory of his tall figure will be associated with the exercise of his surpassing surgical skill, "among the women of culture of the boasted aristocracy of Europe"?

"No one better than he appreciated the delicate nature of a refined woman; no one realized more than he that woman's gratitude surely followed the healing of the broken heart and the broken body, and that she was not without the power of appreciating the beauty of the hand that viewed his qualities of head and heart. We may raise to him a monument, as elsewhere proposed, in that beautiful park of his adopted city, near the fields of his triumphs and the homes of many who loved him well, but at last, for the true valuation of his greatness, we must look to those of the gentle sex, who felt the marvellous nature of his professional work. More precious than the brass and the stone of the loftiest column is the
inscription that commemorates the virtues of the dead.
No monument to the Father of American Gynecology
will be complete unless the inscriptions come from the
grateful heart of a refined and appreciative woman."  
(Kinloch).

In many respects there is a striking resemblance be-
tween the beautiful description which he gave of Mr.
Keith and the personal appearance and peculiarities of
the subject of this sketch.
His "quick action;" his "mind intent on the object
of his pursuit;" and "his haste to accomplish it;" his
"anxiety after he had performed a difficult operation;"
his "musical voice" and his "benevolent and gentle
eyes" (when not scintillating, sparkling, and burning
from a sartorial fire); and his success and fame as a sur-
geon, all seem to speak of him, the announcement of
whose death came to us like the falling of the mighty
oak in the stillness of the forest.

His fame, like that of Keith, was not restricted to his
native country. "The medical profession of the old world
was quick to recognize his greatness, and foreign poten-
tials showered on him the laurel of the "Father of
American medicine," and his name will go down to posterity as the
Father of American Gynecology." (Medical Age.)

"Outside of his special work he was teachable as a
child; although his convictions were strong, his feelings
were intense, and he was impulsive" (Wylie). He was
brief, direct, and brave. He was generous and frank.
He was a master in his art, and a librarian unto himself. His vir-
tues were such as gained for him the respect and admira-
tion of two hemispheres" (Foster).

These, these were some of the facets upon the jewel
that glittered on the heart of J. Marion Sims.
He died of disease of the heart on the thirteenth day
of November, 1883, in the seventy-first year of his age.
A communication from Ontario County concerning the
Code. Made a special order, with other matters under
the same head, for this evening.

A similar communication from Washington County
Medical Society received alike reference.

ARMY MEDICAL MUSEUM AND LIBRARY.

Dr. A. Jacobi, of New York, offered a preamble and
resolution approving of an appropriation for the erec-
tion of a building to contain the records of the library
and museum of the United States Army, and asking for
their endorsement by the State Medical Society. They
were adopted, and orders transmitted to the Committee
on Public Grounds, attested by signatures of the Presi-
dent and Secretary, and the Seal of the Society.

Dr. Vander Poel, of New York, called attention to the
fact that a national committee had been organized to
collect funds for the erection of a monument to

THE MEMORY OF J. MARION SIMS,
and asked that the members of the Society interest them-

later the flap was transposed at the central point. A
steely pin was then passed beneath the nose at the margin
of the lip, and the flaps from each side brought firmly
into contact and held by pins. Another was passed near
the mucous margin and was secured in the same way,
and two small pins were passed through the intermediate
space.
The advantages claimed for the operation were that it
gave an increased amount of adhering surface over that
given by simple straight incision of the lip. The
case was one in which the intermaxillary bone was ad-
herent to the septum at birth, and which was removed
easily. The secondary operation was performed when
the girl was eleven years old.

Dr. Wey, of Elmira, moved that a committee of threebe appointed on the President's address. Adopted, and
the following were subsequently appointed: E. Hutchin-
son, of Utica; G. J. Fisher, of Sing Sing, and David Web-
ster, of New York.

Dr. W. C. Wey, of Elmira, then read a paper (see p.
146) entitled

TWO UNUSUAL CASES IN OBSTETRICAL PRACTICE.
The paper was discussed by Dr. F. A. Castle, of New
York, who referred to a case of uncontrollable uterine
hemorrhage, which was regarded as due to syphilitic
degeneration of the placenta and uterine walls.

Dr. David Little, of Rochester, then read a paper
entitled

PROPHYLAXIS OF SUMMER COMPLAINT IN INFANTS.
He thought that over-feeding was one of the great
causes of what is generally known as "summer com-
plaint." He advised often giving infants water instead of
food when the child cries. For twenty-two years he had
been physician to a children's orphan asylum. Here
there had always been enteric disease until the summer of
1882, when he ordered a change in diet. The infants
were to be fed only every three or four hours and given
plenty of water. There was no intestinal disease during
that season. He had had similar experience the next
year.

Dr. Woodward, of Big Flats, said that persons ought
to take into account the epidemic influences. It is very
well known that in this country since 1882 the mortality
among infants had been less, owing to this peculiar epide-
mic influence.

Dr. Castle, of New York, said that he thought the
teachings of Dr. Jacobi on the subject of infant diet had
done a great deal to lessen infant mortality in the past
few years.

Dr. Ely, of Rochester, said that he wished to em-
phasize the point made by Dr. Little, that enteric trouble
is largely prevented by regulating diet and giving plenty
of water. He instanced a case of a child weighing fifty-
six pounds using twenty-eight pounds of food a week,
and losing flesh steadily from a chronic diarrhea. The
child recovered under modification of diet.

REPORT OF THE COMMITTEE ON PRIZE ESSAYS.

Dr. Rochester, of Buffalo, reported that two essays
had been submitted. To that on "Tubercles of the Breast"
was awarded the Merritt H. Cash prize, and on opening
the envelope the name of Ghislani Durant, of New York,
was announced as the successful competitor. The sec-
ond essay was on "Consumption," and was regarded by
the Committee as worthy of publication.

Dr. A. G. Gerster read a paper entitled,

NEUBER'S DEEP CANALIZATION IN AMPUTATION OF THE
FEMALE BREAST.

By canalization, as devised by Neuber, of Kiel, is
meant a process by which good drainage is afforded to a
wound, shallow or deep, without the use of drainage-
tubes. It is divided into two kinds: shallow, and deep.
Shallow canalization is employed for draining exten-
sive subcutaneous cavities. It is accomplished by means of a punch, like a leather punch, by which elliptical pieces of tissue, $\frac{1}{2} \times \frac{1}{2}$ cubic inch large are cut out. A number of these are made in the skin flap, and they afford excellent drainage.

Deep canalization is intended to afford drainage to the secretions accumulating in the recesses of a deep wound. Absorbable drainage-tubes have been used for this purpose. Nuber devised the method of detaching the skin on each side of a deep wound, so as to make it movable, then turn it into the wound and fasten it at the bottom with cat-gut sutures. The cutis thus forms a funnel which drains the wound. This is called deep canalisation.

The speaker reported three cases where he had applied this method in amputation of the female breast, with removal of the axillary glands. By sewing the skin into the axillary cavity he obtained an excellent drainage and the wounds healed by first intention. The method was simple and required no special apparatus except a punch and some stout cat-gut.

Dr. O. D. PomeroY, of New York, then read a paper entitled:

AN OPERATION FOR CORRECTING DEFORMITY OF THE AURICLE.

The auricle was inserted in front and slightly below the meatus, giving rise to the deformity known as cat's-ear deformity of the auricle. The auricle at its faulty insertion was separated sufficiently far to allow it to be drawn up in the natural position. This incision extended backward, then directly upward in a line with the normal position of the auricle. The upper part of this incision was separated by undermining the skin sufficiently to allow the cut surface of the freed auricle to be attached, and in order that the auricle should have the normal flare the anterior border of this cut surface was pared away. Then it was attached by sutures in the anterior border of the vertical wound previously made, and with the exception of the flap at the vertical border of the auricle, which was placed also posteriorly, the wound being perfectly united at the posterior border, no sutures were necessary.

In front of the meatus, near the faulty insertion of the auricle, was a little cartilaginous elevation, somewhat resembling a rudimentary concha. The skin was dissected from this and the cartilage so pared off as to bring it to a level with the surrounding integument, and the flap of skin was drawn over the top and united with the wound made by the incision which separated the faulty attached auricle. The wound made by separating the auricle from its faulty attachment was closed by sutures, the skin being sufficiently undermined to allow the flaps to slide. There were twenty sutures, representing a vertical line extending upward in front of the meatus about one-half of the distance, and suddenly turning backward and passing up in the direction of the new position of the auricle. Of the twenty sutures three only were passed through the cartilage. The wound was dressed antiseptically. The healing of the parts coapted by sutures in the skin was prompt, the wounds in the cartilage healed a little more slowly. The wounds had entirely united, with the exception of a more than a moderate reaction. No pus formed in either the wound or the suture apertures. Dr. PomeroY then referred to cases which illustrated the innocuousness of sutures in cartilage, the readiness with which wounds in cartilage heal when wounded, and closed with a reference to the literature of deformity of the auricle.

Dr. JACOBI of New York, asked for the experience of the specialists as to whether or not these abnormalities of configuration were anomalies in other parts of the body. He had seen quite a number and had concluded that they are only rarely so complicated.

Dr. PomeroY said that in a certain number of cases arrest of development is found in other organs, but certainly in one-half of the cases there has been no such complication.

Dr. GEORGE B. FOWLER read a paper entitled POISONING BY POTASSIUM CHLORATE.

A brief survey was given of the history of this drug. It had been very popular for many purposes, but now its use was chiefly confined to diseases of the mouth and upper air-passages. An account of the toxicology of the drug was given. The fact that doses of four to six drachms caused serious symptoms was referred to. He related the history of a case of a young woman who had been poisoned by large doses of the potassium chlorate. The urine in this case was very peculiar. It had a specific gravity of 1.056. Under the microscope the red blood-corpuscles appearedcrennated. There was a decomposing product of the haemoglobin, viz., methaemoglobin in the urine. This methaemoglobin, it was found, was the result of the chlorate of potassium upon the blood, and it could be produced artificially by adding a small solution of the chlorate to the blood.

Dr. Fowler gave the further history of the toxicology of the drug, showing its general and local poisonous effects.

Dr. CASTLE, of New York, directed attention to the poisonous effects liable to occur from the local use of chlorate of potash, as in gargles, as it is a decided irritant to inflamed mucous membranes.

Dr. DANIEL LEWIS, of New York, remarked that poisonous effects produced by the drug came mostly from carelessness in physicians in prescribing it, and a like carelessness in druggists in handling it. If used with the care exercised in the use of potent drugs, probably the harm liable to be done by it may be avoided.

Dr. STILLWELL, of Brooklyn, had recognized as one of the varieties of sore throat that produced by chlorate of potash. The remedy is said to be good for sore throat, and certainly it is, but the large pellets prepared by pharmacists were very detrimental.

Dr. Fowler referred to experiments which he had performed on rabbits, the animals dying in convulsions, and examination revealed rupture of the stomach, a fact which he thought had not been mentioned by any observer.

Dr. Piffard, of New York, offered the following resolution WITH REFERENCE TO READING PAPERS.

Resolved, That the Business Committee shall not provide for the reading of papers by persons who are not members of the Society when members are present who desire to read them.

It was offered as an amendment to the By-Laws.

Discussion ensued, and the resolution failed to receive the requisite two-thirds vote to adopt it.

MEMBERS BY INVITATION.

W. S. Tremaine, Professor of Surgery, University of Virginia; T. P. Bailey and J. B. Stonehouse, of Albany; F. A. Anderson, of Messina, St. Lawrence Co.; M. S. Kittinger, Lockport; Peter Faling, Gasport; W. W. Seymour, Troy; S. S. Wallian, Bloomingdale, Essex Co.; G. P. Clark and Alfred Mercer, Syracuse, and Samuel Morrow, Albany.

The Society then adjourned, to meet at 3 P.M.

TUESDAY, FIRST DAY—AFTERNOON SESSION.

The Society was called to order by the President.

Dr. Parker, of Poughkeepsie, read a paper on THE ESTABLISHMENT OF HOSPITALS IN SMALL CITIES.

The writer's aim was to encourage the establishment of such institutions, to give some hints as to how they should be managed, what will be the expense, etc. The primary necessity is to purchase a building, as this avoids...
the perplexities incident to the fluctuating opinion of landlords. This is sometimes difficult to accomplish, on account of neighborhood prejudices against hospitals. Details were given concerning the composition and duties of the house staff, matron, board of trustees, etc. No resident pharmacist is kept, nor medicines, only such as are necessary to meet emergencies. This is economical. The whole expense of carrying on such hospitals as arrived at by comparison with expenses of the Fishkill and Auburn hospitals, is about two hundred dollars a bed. The medicines are under the religious instruction of the clergyman of the denomination to which they belong. This has added to the popularity of the institution.

Dr. Van De Warner, of Syracuse, read a paper entitled

A NEW METHOD OF PARTIAL EXTRICATION OF THE CANCROUS UTERUS.

This method, to which the author had called attention previously, consisted in amputating the cervix and such parts of the cancerous mass as were accessible, then applying chloride of zinc, as taught by Sims, in strong solution, protecting the parts by absorbent cotton and tamponing with iron cotton. Large deep sloughs could be thus brought away. Specimens of sloughs which had been obtained from cases operated upon were shown.

REPORT OF COMMITTEE ON EXPERIMENTAL MEDICINE.

Dr. J. G. Curtis, of New York, Secretary, reported that no bill was introduced into the Legislature for 1883, and the committee recommended that the Society renew its declaration of approval of scientific experiments on living animals for the benefit of the art of medicine.

Dr. L. E. Felton, of Potsdam, read a paper entitled

THE VALUE OF ELECTRICITY IN DIAGNOSIS.

The author was of the opinion that by testing the electro-irritability of muscles in individuals, some valuable points could be obtained in diagnosis. If the irritability was markedly diminished it should suggest disease. Galvanic and faradic currents could be used. The technique of applying these currents was given.

COMMITTEE ON NOMINATIONS.

From the Society at large, E. H. Parker, of Poughkeepsie; First District, Samuel Johnson; Second District, E. C. Tubbs; Third District, W. W. Crandall; Fourth District, L. E. Felton; Fifth District, H. G. DuBois; Sixth District, W. W. Crandall; Seventh District, Darwin Colvin; Eighth District, John O. Roe.

Dr. W. C. Wey offered the following resolution, which was adopted:

Resolved, That the bill to establish a medical faculty of the University of New York be and is hereby referred to the Committee on Legislation, with instructions to report to-morrow, Wednesday, when the regular order for the report of said Committee is reached.

Dr. A. Jacobi read a paper entitled

CONGENITAL LIPOMA.

Numerous cases of congenital development of subcutaneous adipose tissue had been collected by the speaker, and notes of some of them were given. These cases formed the majority of those young children who have an enormous weight. One child whose case was reported had a hand which weighed eight pounds. Four cases in the speaker's practice were related.

In one case, that of a female infant, the left foot, the right thigh, the abdomen, and chest were the seat of lipomatous growths, and there was a vascular tumor on the right side of the chest. The child subsequently died, and was found to have hydrocephaus and peri-nephritis.

In another case there was a lipoma in the lumbar region, complicated with spina bifida.

In conclusion, the speaker said that an examination of all the cases that had been reported in the past century showed that the disease was very rare, many are complicated, some with vascular tumors or dermoid degeneration, or fusion of bone, or cartilage, or spina bifida. They are generally diffused, a few are encapsulated.

Congenital lipomata are found oftenest on the hands or feet, then in the lumbar and gluteal region. In only one case were they found on the head.

The Committee of Arrangements introduced

Dr. N. A. Powell, of Toronto, Ont., who spoke of the advantages which attended the action of a board of medical examiners in his locality.

ORBITAL CELLULITIS.

Dr. T. R. Pooley read a paper on the above subject in which he reported two cases of the idiopathic variety of the affection which terminated favorably under the systematic and persistent use of hot water and pressure bandage chiefly.

The first case was not severe, only affecting the anterior portion of the orbital tissue; in the second case the disease extended to the depths of the orbit. Dr. Pooley reviewed the leading symptoms of the disease, as chill, cephalalgia, chemosis of the lids, sometimes vomiting and epistaxis and occasionally convulsions, with protrusion of the eye, usually sudden, accompanied by limitation of movements of the eye, etc. Operative interference may be required to evacuate pus, which can be done through the orbit or through the lids. An interesting feature in these cases is the change in vision, which may be due to thrombosis of the retinal vessels, both arteries and veins, and disturbance of vision may be due to anamlyopia or amaurosis. The peculiar appearance of the fundus was illustrated by plates from a case which occurred in Dr. Knapp's practice.

Dr. Laurence Johnson read a paper entitled

A PLEA FOR THE PHARMACOPEIA.

The speaker referred to the growing practice among manufacturing pharmacists of foisting all kinds of special preparations, elixirs, pills, etc., upon the medical profession. The manufacturing pharmacist's bundles and packages and travelling agents had become a great nuisance to the physician. Besides this the practice was attended with serious harm. Some of the results were:

It had happened that members of the society had read papers recommending these secret proprietary medicines.

2. The use of these manufacturers' special preparations prevented our obtaining a common standard of reference by which we can compare therapeutic results.

3. In many cases the object of the manufacturers in getting medical endorsement is to finally get their preparations before the public. It is a fact that some of these preparations are now for sale at fancy stores, along with calicos and ribbons.

4. Still another evil was temptation for the physician to experiment with new or useless drugs.

5. Finally, the speaker referred to the impertinence of the manufacturers in furnishing the profession a ready-made materia medica and therapeutics. With their little books and their little pills and boxes it is as easy for a man to practise medicine as with a homeopathic family-book and medicine-chest.

The remedy for all this, the speaker said, was a simple one. Let physicians use the Pharmacopeia and the remedies official there.

It was discussed by Drs. Jacobi, Mittendorf, and Castle.

REPORT OF THE COMMITTEE ON THE PRESIDENT'S ADDRESS.

Dr. E. Hutchinson, of Utica, Chairman, offered the following resolutions:

Resolved, That the President shall hereafter appoint the Business Committee in advance of the Annual Meeting, at as early a period as practicable, for the purpose
of securing scientific work for the next annual meeting of the Society.

Resolved, That the President hereafter shall be a member ex officio of the Business Committee.

Resolved, That the Business Committee be empowered to suggest medical questions for general discussion.

Resolved, That in case of the occurrence of vacancies in any of the committees the President shall have power to fill such vacancies.

The report was accepted and, on motion of Dr. W. M. Carpenter, of New York, was referred to the Committee on By-Laws with the recommendation that the Committee report them to the Society as amendments to the By-Laws.

A biographical sketch of Morgan Schneider, M.D., by Dr. Alex. Ayers, of Fort Plains, was read by title.

Dr. Fisher, of Sing Sing, offered a resolution making provision for

A COMMITTEE ON NECROLOGY.

It received the same reference as the above resolutions, to the Committee on By-Laws.

Dr. Vanderwer, of Albany, then read a paper (see p. 151) on

OPERATIONS FOR CLOSURE OF THE HARD AND SOFT PALATE.

It was discussed by Drs. Fowler, of Brooklyn; E. Hutchinson, of Utica; A. G. Gerster, of New York; N. A. Powell, of Toronto, and S. B. Ward, of Albany.

Dr. David Webster, of New York, then read a paper on

SYMPATHTIC OPHTHALMIA.

[It will appear in a subsequent number of The Record.]

It was discussed by Dr. Mittenbrough, who insisted strongly upon the point that an injured eye, already blind, should be removed at once, and not wait until inflammatory action has set in in the opposite eye.

Dr. Daniel Lewis read a brief paper entitled, THE VALUE OF HORSE-HAIR AS A SUTURE.

The speaker had used horse-hair in place of cat-gut and silk in many forms of operation and with great satisfaction. In operations upon the scalp, the breast, in amputation of the fingers, and in other cases, he had used horse-hair sutures with great success. He thought it would be also useful in gynecological operations.

Dr. E. M. Moore, of Rochester, spoke of the great value of horse-hair as material for drainage. It was non-irritating and it could be removed gradually by hair.

The following papers were read by title and referred to the Committee on Publication: "Dysmenorrhcea: Its Treatment by Dilatation," by Dr. W. W. Potter, of Buffalo; "Two Cases of Rupture of the Heart," with pathological specimens, by T. H. Squire, Elmira; "Biographical Sketch of James Rushmore Wood, M.D., L.L.D.," by Dr. Frederick S. Dennis; "Biographical Sketch of the late Dr. G. W. Bradford," by Dr. E. C. Gamey; "The Biographical Sketch of the late Dr. J. F. Jenkins," by Dr. G. J. Fisher, of Sing Sing; "The Medical Society of the State of New York in its Relation to Science," by the late Dr. E. Harris, of Albany; "Biographical Sketch of Dr. Jas. S. Bailey," by Dr. F. C. Curtis, of Albany.

MEMBERS BY INVITATION.

The Society then adjourned to meet at 8 o'clock.

TUESDAY, FIRST DAY—EVENING SESSION.

THE NEW CODE SUSTAINED BY A MAJORITY VOTE.

The Society being called to order,

Dr. Piffard, of New York, moved that the resolution of the Ontario County Medical Society, endorsing the Old Code, be called up on the table, and that that Society be informed that the By-Laws adopted by the county societies which conflict with those of the State Society are not legal or binding. The motion was carried.

Dr. Baker, of Niagara County, read some resolutions from his County Medical Society, to the effect that any change in the Code of Ethics of the State Medical Society ought not to be made until some action had been first taken by the American Medical Association.

These resolutions were received and entered on the minutes.

Dr. Didama's resolution abolishing the New Code was then read.

Dr. Rochester moved the adoption of this resolution. He then made a temperate speech advocating harmonious action for the sake of preserving the Society and its adherents.

Dr. Didama read some remarks advocating the passage of his resolution. He spoke of the peaceful condition of the Society before the New Code was adopted, and of the change which had taken place since then. He said that the New Code party had brought the Society into disrepute throughout the English-speaking world; they had broken off the Society from representation in the American Medical Association.

Dr. Roosa, of New York, said that it was the intention of the New Code party, which was in the majority in the State, to let the vote be taken without discussion. To-night, however, a new element had been brought up in the discussion. The Old Code party had held up a threat that the Old Code were not re-adopted and its adherents would secede. The speaker said that the representatives of the New Code had received letters from distinguished men in nearly every State, which urged New York to stand by its position, and assuring them if they did that they would soon receive support from other places.

Dr. Moore, of Rochester, read an editorial from the Journal of the American Medical Association, in which the view was held that the action of the New York State Society in enacting a new code was an act of secession against the American Medical Association.

The result of the vote was 105 ayes to 134 nays, which sustained the action of the Society taken in 1882 and maintained in 1883.

Dr. Roosa then brought up the subject of his declaratory resolution, or no code.

Dr. A. Jacobs moved that it be read and adopted in place of the present New Code.

Dr. C. R. Agnew gave a history of his action in connection with the adoption of the New Code, saying that in framing it the committee only made the by-laws in accord with the laws of the State.

He believed that the Society would yet be represented in the American Medical Association, but it could never be expected that the State Society should send delegates in humiliation and repentance and in violation of the statute of the State to that Association.

Dr. Baker, of Niagara County, made a speech in advocacy of the National Code, repeating some of the older arguments.

The ayes and nays were called for.

On motion, the Society adjourned.
WEDNESDAY, SECOND DAY—MORNING SESSION.

The Society was called to order at 10 A.M., by the President.

Prayer was offered by REV. WALTER D. NICHOLLS, D.D. The Committee of Arrangements introduced Dr. N. S. Babbitt, of North Adams, delegate from the Massachusetts Medical Society.

The TREASURER'S REPORT,

presented by DR. C. H. PORTER, of Albany, Treasurer, showed a balance in the treasury of $1,462.92. The report was received and referred to an Auditing Committee, consisting of Dr. A. M. Jacob, John T. O'Meara, and Dr. C. M. Bell. The Committee subsequently reported that they had examined the accounts of the Treasurer and found them correct.

The Committee appointed to endeavor to secure a room for the Society in the new capitol building reported that suitable accommodations could not at present be secured for the same.

The Committee on Reproduction of the Transactions of the Society reported, through Dr. F. C. CURTIS, of Albany, that the reproduction is not at present desirable.

Report received and the committee discharged.

Dr. W. ELY, of Elmira, for the

COMMITTEE ON BY-LAWS,

read a report. He stated that in many cases the by-laws of the county medical societies were badly drawn, and were not in accordance with the laws of the State or the By-Laws of the State Society. The Committee gave a list of only twelve county societies whose by-laws were correct. A resolution was offered instructing the Committee to draw up and have printed a scheme of by-laws to be distributed to the county societies for their instruction.

COMMITTEE ON PRIZE ESSAYS.

Dr. W. S. ELY said that, by some mistake, the report of the Committee already submitted to the Society was signed by Dr. Moore, of Rochester, who is not a member of the Committee, and not signed by Dr. Potter, of Buffalo, who is a member of the Committee. At his request the report was referred back to the Committee for further report.

Dr. A. JACOB read the report of the

COMMITTEE ON PREVENTION OF CRUELTY TO CHILDREN.

He referred to the near completion in New York City of the Hospital for Contagious Diseases. He urged the passage of a resolution appointing a committee of three to help secure the passage of a law forbidding the employment in factories of sickly children, especially those suffering from anemia, scrofula, phthisis, bronchitis, etc.

The report was adopted.

Dr. PIFFARD, of New York, offered the following resolution, which was adopted:

Resolved, That the Secretary be authorized to have printed a sufficient number of copies of the proceedings of this Society (not "Transactions") to supply every member of county societies in affiliation with this Society, and that the Secretary be instructed to send a copy to each member of the several county medical societies.

Dr. E. V. STODDARD read the report of the

COMMITTEE ON HYGIENE.

This described the work of the State Board of Health. It urged the use of more careful and energetic measures for quarantining cases of measles and scarlatina, especially in camps. The local sanitary boards were also urged to be more attentive in this respect.

To the report was added the report of the Committee

The report was adopted.

Dr. F. R. STURGIS, for the Committee on Legislation, read a report covering the subject of the

PROPOSED NEW MEDICAL LAW.

A bill was read which was substantially like that known as the Erie County bill, and it was recommended to the Society for endorsement.

Dr. STURGIS also, as a supplementary report, read another bill, which had been drawn up by those interested in the colleges. It differed from the bill recommended by the Society chiefly: 1, in that it appointed a medical faculty without reference to sects; 2, in that this medical faculty was not given a licensing power, but was simply allowed to attend the examinations of medical students by their professors, and take back a report to the Regents of the University of the State of New York.

Dr. HOPKINS, of Buffalo, made a brief speech, urging that the Society endorse the bill.

Dr. A. L. LOOMIS then took the floor and made an elaborate and forceful argument against the Committee's bill. The points which he made against it were: that it appointed a mixed board and thus recognized homoeopathy and eclectic; that it was probable that the board would be subject to political influences; that difficulties would be had in finding proper men for the faculty; that it would injure the colleges and the educational interests in the State. Dr. Loomis made an eloquent appeal for harmonious feeling between the colleges and the profession.

Dr. D. B. ST. JOHN ROOSA followed in reply, and made an argument which was listened to with great attention, and was frequently interrupted by applause. Dr. Roosa spoke in the warmest terms of the high standing and valuable work of the medical colleges. They had been most essential in raising the status of the American medical profession. He thought that the time had come now, however, when, unless something was done, these institutions would undo the good they had already accomplished. He stated that the bill advocated by Dr. Loomis really eviscerated the bill and would result in nothing at all. The college bill provided for an unmixed board, but it was very well known that with such a provision the bill could not have the slightest chance of passing. He thought that there would be no more difficulty in getting nine good men as examiners, than the colleges had in getting their professors. He stigmatized the medical faculty constituted by the college bill as being nothing more than a "tea-drinking convention." It seemed as though the advocates of this bill were seeking to kill all legislation in order to protect their own interests. The speaker excited much applause by referring to the fact that he had met, before the Legislative Committee, Dr. Loomis and Dr. Flint shoulder to shoulder with Dr. R. V. Pierce and Dr. Gunn. The function of the medical colleges, said Dr. Roosa, was to teach; the licensing should belong to a responsible and disinterested body, that is to the State.

Dr. H. G. PIFFARD reviewed the history of the medical colleges of the State and of the legislation regarding the power of licensing. He then took up the two bills reported by the committee and criticized several points in them. Dr. Piffard was opposed to having a mixed board. He did not like either of the bills, and hoped that a committee would be appointed to arrange a new one.

After some general comments on the subject by Drs. Jacob, Dalton, Sturgis, Agnew, and others, it was made a special order for the report.

On motion the bill of expenses of the Committee on Legislation was referred to a committee of three for auditing.
MEMBERS BY INVITATION.
T. W. Nellis and W. J. Nellis, of Albany; A. M. Smith, of Williamstown, Mass.; H. E. Allison, of Waterloo, N. Y., and M. J. Roberts, of New York. The Society then adjourned to meet at 3 P.M.

WEDNESDAY, SECOND DAY—Afternoon Session.
The Society was called to order at 3 P.M. by THE PRESIDENT, the special order from the morning session being before the Society.

Dr. J. W. Howe said that he opposed the medical bill of the committee. He believed that it had been drawn up hastily, and without consultation with the colleges or the representative men in the State. He believed that there should be a conference upon the matter. The speaker thought that the State Medical Society could better take charge of this matter, and to that end he offered a resolution providing that the State Society appoint a commission to attend and take cognizance of the examinations at the medical colleges, and report to the Society.

Dr. J. C. Dalton seconded Dr. Howe’s resolution. He said that he did so because something of this kind had been in his mind before. He was entirely opposed to any legislative action at present. The committee’s bill separated the power of granting diplomas and licenses, but he did not see how this could do any good. The proposed Board of Examiners would be paid by the fees of those applying for license and would be under the same stress to grant licenses as the faculties of colleges are. He thought that the teachers in the colleges were much more competent to examine the students for receiving licenses. In some colleges, at least, no work received more conscientious attention than that of examining the students. The speaker then criticised the mixed character of the proposed Board. If created, it would oblige graduates in regular colleges to get one vote or more from a homœopath or eclectic.

Dr. Hopkins offered a resolution that the Society recommend, as a general measure, the creation of a Board of State Medical Examiners.

Dr. Vander Poel moved as a substitute that the following gentlemen be appointed a committee to whom the whole matter be referred with power: Drs. Loomis, Roosa, Sturgis, Van de Veer, A. E. M. Moore, Austin Flint, Jr., and Jacobs.

Dr. Jacobs suggested that a larger expression of opinion should be invited from members who had not spoken.

Dr. Moore, of Oneida County, said that action ought not to be taken at present upon the matter. The County Societies had not yet given the matter consideration.

Dr. Howe’s resolution was, by vote of 31 to 30, laid on the table.

Dr. Rochester said that he believed in a State Medical Board, but urged postponement for a year.

On an amendment to Dr. Hopkins’ resolution, offered by Dr. Piffard, it was finally voted to refer the whole matter to a committee composed of the Legislative Committee and Drs. Loomis, Van de Veer, and J. G. Curtis.

THE COMMITTEE ON PRIZE ESSAYS.

Dr. Rochester, of Buffalo, made a majority report recommending the awarding of the Merritt H. Cash Prize to the author of an “Essay on Tubercles of the Breast,” Dr. W. W. Potter, of Buffalo, read a minority report, in which he opposed awarding the prize to this essay because, though an excellent one, it contained little original material.

Dr. S. O. Vander Poel, of New York, said that the same essay had been offered before the New York County Medical Society and had been rejected. He therefore moved that the minority report be adopted. The motion was carried and the prize not awarded.

Dr. W. F. Mitterdorf, of New York City, read a paper entitled

FOERSTER’S METHOD OF RIPENING CATARACT.

[It will appear in full in The Rxcord.]

Dr. W. F. Sheehan, of Rochester, read a paper entitled

HOUSE SANITATION AS IT IS AND AS IT SHOULD BE.

The dangers of ground-air in the cellars, and the relations of it and sewer-gas to diphtheria, typhoid fever, and other systemic diseases were dwelt upon. A method of properly providing against this was described.

Dr. A. N. Bell took grounds against the speaker in his recommendation to have cellars bricked and cemented. He also advised ventilating tubes to be carried up straight without ending in a goose-neck.

Dr. Milton J. Roberts, of New York, read a paper entitled

THE MECHANICAL TREATMENT OF HIP-JOINT DISEASE.

This paper will appear in full in The Rxcord.

Dr. Geo. B. Fowler, of Brooklyn, said that the views which Dr. Roberts presented corroborated the opinions which he had drawn from his own experience. He moved that Dr. Roberts’ paper be referred to the Committee on Publication.

Dr. A. M. Phelps, of Chautauqua, read a paper on

SYNOVITIS OF THE KNEE- AND ANKLE-JOINTS,
and exhibited a variety of apparatus for treating the disease and preventing deformity. Sayre’s, Stillman’s, and his own apparatus were described, the latter of which were notable for their simplicity of construction.

REPORT OF COMMITTEE ON BY-LAWS.

Dr. Wey further reported on the report of the Committee on the President’s Address, adversely with reference to the suggestion concerning the appointment of the Business Committee in advance; adversely on the resolution making provision for the election of a committee on Sections; favorably to authorizing the Treasurer and Secretary to act temporarily as the Committee on Credentials during the evening immediately preceding the first morning session of the annual meeting, until the regular Committee is appointed by the President.

Dr. C. L. Dana, of New York, read a paper entitled

MORBID DROWSINESS AND SOMNOLENCE.

He had collected from medical literature and his own experience sixty cases of morbid somnolence. These were cases where the condition was not due to organic disease or insanity, but was a neurosis.

The various sleeping states he divided into three classes: One was of epileptoid origin; here the attacks of somnolence took the place of absence or petit mal seizures. Another class of patients were plainly hysterical; in some of these the sleeping states were of a mesmeric kind. A third class included those forms of functional morbid somnolence not to be classed with epilepsy, hysteria, or mesmerism; of this character he reported several cases.
A sketch of the etiology, symptoms, course, prognosis, and treatment was given.

MEMBERS BY INVITATION.

C. Devol and D. C. Case, P. J. Keegan, A. B. Huestes, and A. Fowler, of Albany; Wm. H. Robb, Amsterdam, and Anthony TenEyck, of Defrietville.

The Society then adjourned, to meet in the Assembly Chamber at 8 o'clock, to listen to the Anniversary Address.

WEDNESDAY, SECOND DAY—EVENING SESSION.

The Society met, pursuant to adjournment, in the Assembly Chamber at 8 P.M., and was called to order by Dr. H. G. P. Spencer, of Watertown, Vice-President.

The President then delivered

THE ANNIVERSARY ADDRESS

(see p. 144), which was listened to by a large and appreciative audience, and for which, on motion by Dr. Robert Frasier, of Camden, he received a vote of thanks.

After the delivery of the address the members adjourned to the banquet, where catables were discussed and speeches made up to a late hour in the evening.

THURSDAY, THIRD DAY—MORNING SESSION.

The Society was called to order by the President, after which prayer was offered by the Rev. Horace Stanton, D.D.

The Committee on Publication reported that one thousand copies of the "Transactions" were printed at an expense of ninety cents apiece for members.

A resolution was adopted authorizing the Secretary to wrap and send by mail the "Proceedings" to members of the county medical societies, according to the list in volume of "Transactions," 1883.

THE MANAGEMENT OF FACE PRESENTATIONS.

Dr. E. L. P Artidge, of New York, read a paper on the above subject, in which he advocated the conversion of a face presentation into vertex by the hand of the attendant. Several cases were reported in which this had been done. The operation consists in chloroforming the patient and introducing the hand into the vagina. Pass two fingers over the occiput, press firmly against it, and draw downward. Flexion of the head will quickly take place. Circumstances especially favorable to the operation are head movable at brim, or easily made so by lifting cervix upward, and nearly dilated os and unbroken membranes. In most cases of labor a period is reached when these conditions are found.

IS CONVERSION OF FACE-PRESENTATION INTO VERTEX DESIRABLE?

Statistics show that it is. Some cases show a tendency to return to the face after the vertex has been brought down; therefore watch each case, in order to early observe such tendency, and, if observed, apply forces to engage the head; then leave the case to nature. If it should happen that all our efforts are fruitless, the case is not further complicated by them. We simply have the original condition of affairs. Our methods are either uncertain or dangerous; if undertaken when the cervix is undilated, it may be lacerated, or if the operation is successful, we are liable to return of the face presentation during the time before labor can be completed. If the face has descended into the pelvis and cannot be lifted up, the face presentation may be produced by manipulation. The method of Seltz is ingenious, but too uncertain, as the change is attempted by manipulations through the thick abdominal and uterine walls.

Dr. A. Jacobi, of New York, read a paper on"Arsenic and Digitalis in Pneumonia," which will appear in a future number of The Medical Record.

The paper was discussed by Dr. F. R. S. Drake, of New York.

THE REPORT OF THE NOMINATING COMMITTEE

was next made and adopted as follows:

For President—B. F. Sherman, Ogdensburg; Vice-President—P. R. H. Sawyer, of Bedford; Secretary—Wm. Manlius Smith, Syracuse; Treasurer—Charles H. Peters, Albany; Journal Secretary—Southern District—A. Castle, G. H. Fox, David Webster; Eastern District, E. D. Ferguson, N. L. Snow, Le Roy McLean; Middle District, A. Churchill, J. K. Chamberlyne, Robert Frazier; Western District, T. F. Rochester, B. L. Howe, Theodore Demon; Committee of Arrangements—S. B. Ward, Albany; W. S. Ely, Rochester; E. L. Partridge, New York; Committee on By-Laws—W. C. Wey, Elmira; A. Hutchinson, Brooklyn; William Manlius Smith, Syracuse; Committee on Hygiene—E. V. Stoddard, Rochester; Caleb Green, Homer; E. Hutchinson, Utica; W. H. Bailey, Albany; A. N. Bell, New York; G. J. Fisher, Sing Sing; W. F. Sheehan, Rochester; Committee on Legislation—H. G. Piffard, Daniel Lewis, New York; H. R. Hopkins, Buffalo; Committee on Medical Ethics—A. J. B. Black, New York; A. Matthewson, Brooklyn; J. W. Whitebeck, Rochester; Committee on Prize Essays—W. W. Potter, Buffalo; A. Hutchinson, Brooklyn; W. S. Ely, Rochester; Committee on Publication—W. M. Smith, Syracuse; C. H. Porter, Albany; H. D. Didams, Syracuse; Censor College of Medicine Syracuse University, J. P. Creveling.

PERMANENT MEMBERS.

DELEGATES TO INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

DELEGATES TO STATE MEDICAL SOCIETIES.

The officers were elected by affirmative ballot cast by the Secretary.

Dr. S. B. Ward moved a vote of thanks to the State Agricultural Society for use of hall.

Dr. W. M. Carpenter moved a vote of thanks to the President for the able, dignified, and impartial manner in which he discharged his duties.

The President responded.

Dr. B. F. Sherman moved a vote of thanks to Committee of Arrangements and a similar motion was made by Dr. A. Jacobi on the Business Committee, after which the Society adjourned.

SURGEON-GENERAL OF THE NAVY.—The term of office of Surgeon-General Wales as Chief of the Bureau of Medicine and Surgery expired at noon January 26th. Mr. David Carrigan, chief clerk of the bureau, performs the duties of the office until the appointment of a Surgeon-General.
Correspondence.

CONCERNING DIASTASE IN A MALT EXTRACT.

To the Editor of THE MEDICAL RECORD.

Sir: In a recent article in THE RECORD I called attention to the large amount of diastase in a certain malt extract, and in so doing decried the preparations of other manufacturers. In common with other physicians and chemists, whose reports will soon be made public, I was deceived by the specious argument and illogical test of a commercial agent. I was unwilling to seem to be even distrustful of the representative of a large manufacturing pharmacist. Elaborate experimentation, and the exhaustive analyses of Professors Chittenden, Haines, Cole, Harrington, Prescott, and others, together with personal communications from professional men in different parts of the country, convince me of my error. I find that samples of the commended article, bought in open market, do not at all correspond with the samples which the agent used in my office, and which he affirmed he had bought out of stock. This statement of his I believe to be untrue, as the general run of this malt is deficient in diastatic action, and at least one hundred per cent. less powerful than maltine, which I described as inert. I am very glad to confess my error, and those who were equally deceived with myself will understand how it arose.

Horatio R. Bigelow, M.D.

LEAD-POISONING FROM A NEWSPAPER PRESCRIPTION.

To the Editor of THE MEDICAL RECORD.

Sir: On December 7, 1883, I admitted to this institution the following case: Peter B., aged forty-two; widower; laborer; complaining of cough, debility, and severe pains in the abdomen and extremities. Six months since he began to lose appetite and grow weak. Debility progressed until one month before admission, when he began to cough and was obliged to cease work. Reading in a paper that "sugar of lead" was good for his disease he purchased some of the drug and took, as directed by the paper, "as much as he could lay on the point of his tongue at a time" for nearly three weeks. His knife was a large one and he must have taken several grains per diem. On admission he presented the physical signs and symptoms of phthisis. He also suffered from severe abdominal pains or "cramps," and pains in shins. There was partial extensor paralysis and blue-black, foul gums and teeth. Abdomen tense and very tender. The abdominal recti refused to respond to electrical stimulation at first. He had had no stool for several days. A hot water enema was administered and immediately regurgitated. He was then thoroughly purged with saline followed by the systematic use of opium, electricity, and potassium iodide. At present he is slowly gaining in strength, and the symptoms of lead toxemia are gradually disappearing. The debility incident to pneumatic disease will probably prevent complete recovery.

I do not advance the above as an exceptional case. It is scarcely probable that any physician of experience has failed to meet disease induced or aggravated by treatment recommended in the popular press of the day. The injury done by so-called "patent" medicines is sufficiently notorious; but when the newspapers recommend the indiscriminate use of powerful poisons, it is certainly matter for regret that there is no restraining legislation.

Louis C. Wood, M.D.

A PLAN TO RELIEVE THE FREE CLINIC ABUSE.

To the Editor of THE MEDICAL RECORD.

Sir: I have read with interest the articles which have recently appeared in THE MEDICAL RECORD "commenting upon the free clinics" and "free dispensary system." These charities are grossly abused in a fact which needs no elucidation. The question of the hour is, How shall this abuse be prevented? I have the following plan to suggest, viz.: Let those who are interested form an association, divide the work, canvass the city, secure the co-operation of every doctor on Manhattan Island, and as many of the neighboring physicians as possible. When this is accomplished, let the trustees as managers of every institution where free medical or surgical aid is given, be requested to co-operate with "The Charity Organization Society." That society undertakes to investigate all cases applying for aid. The plan is very simple. Pat Flynn applies at a dispensary for medical or surgical aid: his name, age, occupation, and address are taken; he is relieved for a time, but his name is sent to the nearest district office of "The Charity Organization Society," with a request to investigate. If they find him worthy of relief, he continues to receive it; but if they find that he can pay even a moderate fee, notice is at once sent to every dispensary in the city, and henceforth Pat Flynn must pay for his treatment. This method will save a vast amount of work and some expense; but if every practitioner in New York City will contribute two dollars per year for five years, I feel sure that the desired result will be attained. Will the profession co-operate?

Yours very truly,

J. L. Barton, M.D.

456 Lexington Avenue, New York,
January 19, 1884.

Obituary.

ELISHA HARRIS, A.M., M.D.

Few members of the medical profession were better known or more widely esteemed than Dr. Elisha Harris, who died from peritonitis, at Albany, on February 1st, at the age of sixty.

Dr. Harris was born at Westminster, Vt., in 1824. He received a common school education, and after several years of teaching graduated in medicine at the College of Physicians and Surgeons in 1849. Lafayette College subsequently conferred upon him the honorary title of Master of Arts. Soon after beginning the practice of medicine he married, in the autumn of 1849, the only daughter of the Rev. Dr. Josiah B. Andrews. She died in 1867, leaving no children, and from the date of her death Dr. Harris gave all his time to the public service in various capacities.

Dr. Harris' first entrance into the public service was in 1855, when he was made Superintendent and Physician-in-Chief of the Quarantine Hospitals at Staten Island. To him was intrusted, in 1869, the construction of a floating hospital to be anchored below the Narrows, facing the open sea. His mastery of the sanitary problems connected with the New York quarantine station resulted in the establishment of the present system of quarantine defences in all their important details. When the "Army of the Rebellion" marched to the Malvern Hills in connection with the Rev. Dr. Henry C. Bellows and others, became interested in the National Sanitary Commission, and he was for nearly five years a Sanitary Commissioner. The railway ambulance was exclusively his device, and proved of such value that, in 1867, at the Exposition Universelle, in Paris, he was awarded a bronze medal. A silver medal was given him for the same ambulance by the Société des Secours aux Blessés. The
and President. Into the work of this association he entered with his whole soul, devoting all the time he could spare to the advancement of its aims and interests.

Dr. Harris was also widely known as a philanthropist. He was for many years identified with the Prison Association, for the care and reformation of discharged convicts.

Dr. Harris was also identified with the Association for Improving the Condition of the Poor, and was a member of the County Medical Society, the New York Academy of Medicine, the Physicians' Mutual Aid Association, the Society for the Relief of Orphans and Widows of Medical Men, and the Public Health Association of New York. He was also an active or honorary member of various other associations and societies in this country and Europe. He was consulting physician to the country branch of the Nursery and Child's Hospital. He was a voluminous writer of works on sanitary and philanthropic subjects, and also on questions relating to vital statistics.

Army News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 26, 1888, to February 2, 1888.

ALEXANDER, CHARLES T., Major and Surgeon. So much of par. 7, S. O. 211, September 14, 1883, as directs him to report in person to the Commanding General Department of the Missouri for duty, is revoked, and he will, upon the expiration of his present leave of absence, proceed to St. Louis, Mo., and assume duty as Attending Surgeon and Examiner of Recruits in that city.

S. O. 21, par. 1, A. G. O., January 25, 1884.

ELBREY, FREDERICK W., Captain and Assistant Surgeon. Present leave of absence extended six months.

S. O. 24, par. 9, A. G. O., January 25, 1884.

BICHLORIDE AS AN ANTISEPTIC.—The combination of bichloride of mercury with chloride of sodium, which makes the antiseptic permanent, is now the one which is being used in our hospitals. The combination, we believe, was first suggested by C. Amend, a chemist of this city.

DR. LYMAN'S ARTICLE ON APPOLOGY.—Dr. W. J. Brandt, of Brooklyn, N.Y., writes: "In perusing Dr. Lyman's article on 'Apology' in The Medical Record of January 12th, I find that he states, in classifying his symptoms of the differential diagnosis between the coma of positive hemorrhage and that due to opium-poisoning, that in the latter the absence of glycosuria and albuminuria would render a diagnosis easy. He is mis-
guiding many who may not be aware of the fact that after a full dose of opium we have a condition of temporary glycosuria (artificial diabetes). Confirmatory of my remarks I quote Foster ("Text-Book Physiology," p. 435, book ii., chap. v., 1880), where we find the following: "A very similar diabetes is seen in carbonic oxide poisoning, and is one of the results of a sufficient dose of morphia or amyl nitrite."

The Trials of a Country Practitioner in a Cold Region.—Dr. T. J. Hutton, of Fergus Falls, Minn., writes: "Your postal received. In reply, I have consulted many to-day as to the temperature on the night of January 17, 1883. All agree that it must have been somewhat lower still than — 60° on that night, for at 10 o'clock in the forenoon of the 18th the spirit thermometers, which indicate but — 52°, were still congealed. On the night of the 4th inst. it must have run equally low, for at 11 a.m. if recorded — 44°. My dear doctor, we are accustomed to such ‘airs,’ but as it seems to have for you, an element for a novel, I enclose you an old photograph of myself about to go on one of these country excursions.

And if we met and you had an hour or two of leisure, I could treat you to many queer experiences on such calls—especially such midnight calls. How many times I have resorted to natural languages—no interpreter within twenty miles! How often I have slept in a sour, greasy, buggy bed! How often the road was crowded—perhaps on the foot of the bed—has awoke me in the morning! How often missed meals, so filthy the houses, hotels twenty miles distant! How often benumbed so in long midnight midwinter rides that I could not even get out my pocket-flask, so stiff my hands and fingers! How often lost by night on the prairie—in winter, too—whew! in the high wind, the blood curdling cold!—and how—far more out winter nights—getting lost by day is bad enough in winter. My last ‘lost’ was last Friday, returning twenty miles from a diphtheria call. The road taken made the return trip over thirty miles. Sat five hours and thirty-five minutes in the cutter, temperature 30° below—but that was mild! Truly

"Who never ate his bread in sorrow,
Who never spent the midnight hours
Weeping and watching for the morrow—
May never know a change.

A Suggestion to Improve the "Index Medicus."—Dr. F. A. Castle, of this city, writes: "Your recent criticism of the Index Medicus leads me to suggest a plan whereby the medical profession may continue to possess the information furnished by that periodical, in case the present mode of publication has to be abandoned. There are already a sufficient number of special journals published in this country to very nearly cover the field embraced by the Index Medicus, and it would be a simple matter, now that the Index has been published for several years, to estimate the probable demands for space in one journal of each class. The special journals whose aim it is to furnish their readers with a review of the literature of their topics, might profitably include so much of the Index Medicus matter as belongs to them, and pay their pro rata of the expense."

Contagious Diseases in Animals.—The Commissioner of Agriculture, Dr. George B. Loring, called at Chicago a conference of representatives of all bodies interested in the animal industries of the United States. This convention met on November 15th and 16th ult. It discussed the subject of contagious diseases among our domestic animals under the following heads: (1) The extent to which they prevail in this country; (2) the methods of their introduction and spread; (3) the methods by which they may be eradicated or isolated; (4) the efficiency of existing legislation. The convention met during the progress of the annual fat-stock show and other live-stock meetings.

Voluntary Inhibition of the Heart's Action.—Dr. J. Ferguson, of Toronto, Canada, reports a case of this kind somewhat similar to that mentioned by Dr. Brooks in The Record of January 5th. The example was that of a healthy physician, who had the power of controlling his heart's action by an effort of the will. This he used to do occasionally to some of his medical friends for the sake of illustration. Fearing lest he might cause nerve derangement of the organ he abandoned the habit.

Another View of the Matter.—Dr. J. Cochrane, of Lowell, Mass., writes the following protest: "In your issue of December 2nd, there appeared what you were pleased to term a 'Suggestive Item,' written by Dr. F. A. Tuttle, on the separation of matter and force. As a reader of The Record I feel called on to protest against such an article; it is neither scientific nor medical; it is brimful of just such stuff as makes us the laughing-stock of British and continental scientific men, e.g., what thinker, medical or not, humiliates himself by calling ‘in the supernatural’ when puzzled? Then he speaks of mind being ‘a phase of force.’ How can that which creates be ‘a phase’ of its own effect? If force and matter, their correlations and dissipation, are ‘awful’ mysteries, it is absurd to assert, in the same breath, that these awful mysteries are all founded on that one unit, the irretrievability of protoplasm. How does he know that they are? Or is he only stating what is true, when he afterward destroys the ‘force’ of his statements and contradictions, by saying that he does not know the ultimate nature of matter? When did he discover that ‘kidney-cells’ ‘lose’ that strychnin and morphia are ‘poisonous’? The self-contradictory, nonsensical statements will not settle a subject which calls for the highest, clearest thinking and investigation. "Metaphysical moonshine" is a great deal clearer than the light he intends to throw upon the subject. Besides, such an article is an indirect insult to those of your readers who are religious. It would be better to write nothing than pretend to know an ‘awful mystery,’ more especially when medical gentlemen look for science and reason in your excellent columns."

[We think that if Dr. Cochrane will carefully rephrase the offensive item he will not find it so contradictory or unsuggestive as he supposes. So far from its being likely to make a ‘lughing-stock’ it will raise the subject from the standpoint taken by the modern school of psycho-physiology.—Ed.]

Iodoform in Pneumonia is highly recommended by Dr. R. Singleton Smith, also by Semmola and Dreshfeld. The temperature falls, strength increases, and expectoration diminishes. The dose is from one to five grains, from three to five grains daily. Tonic effects after long-continued administration must be looked out for.

The Opening for Physicians in the Northwest.—In a letter to Dr. C. Henri Leonard, Dr. John Garrow, of New Westminster, B. C., writes of the prospects for young (and old) doctors in the Northwest. He writes: "Timber is king, and for men of capital, language in the manufacture of lumber, and enough, hardy, honest farmers, it is the place for excellence. A great number of professional men have come who do not directly depend on their present practice; they having money are speculating. Some, too, have come on account of health, either to benefit their own or that of some members of their family. Of course such ones are not very disappointing, as those who have a professional gain that these are not a humble breed. Fearing lest he might cause nerve derangement of the organ he abandoned the habit.

Everywhere it is the same."

Original Lectures.

ON THE

METHODS OF STUDYING THE BRAIN.

ABSTRACT OF THE CARTWRIGHT LECTURES, DELIVERED BEFORE THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, FEBRUARY 2, 4, AND 6, 1884.

BY BURT G. WILDER, M.D.,
PROFESSOR OF PHYSIOLOGY, COMPARATIVE ANATOMY, AND ZOOLOGY IN CORNELL UNIVERSITY, AND OF PHYSIOLOGY IN THE MEDICAL SCHOOL OF MAINE.

LECTURE I.

(Concluded from page 144.)

The lecturer here quoted from Tuke and Bucknill, to the effect that "in all departments of investigation, it is right to commence with the study of that which is common, simple, and regular, and then to proceed to inquire respecting that which is unusual (complex), and irregular."

He also read the following quotation from the novelist G. P. R. James: "Whatever impressions are intended to be produced on the mind of man are always best received when addressed through common associations. We must refer to something that is habitual and pleasing." These statements are eminently applicable to the study of the brain. It would be well, therefore, to preface the examination of the simpler animal brains, or those of embryos, by the study of schematic diagrams, representing the brain in various stages of complexity. These in turn may be made more intelligible by the prior reference to analogous modifications of familiar objects.

In accordance with this suggestion, the encephalic cavities may be likened to the apartments of a house.

The primary components of every room are the walls, and the spaces which they inclose. The walls are specially named floor, sides, and roof. There are communications between each room and those adjoining.

Any single room may be extended in one or more directions, either symmetrically or without any such regularity.

The walls may also be thickened uniformly or locally. In the former case, the room itself might be reduced to a mere passage. In the latter, the original space might be transformed into an irregular labyrinth.

So, too, one apartment may be extended upward so as to overshadow the one below it. The larger may be made to overlap the smaller, and its thicker floor become so attached to the roof on which it rests that removal of the former would involve a tearing off of the latter.

To complete the picture, we may imagine a house consisting of such a series of apartments to be completely enveloped by a continuous layer of tarred paper, and its rooms to be lined throughout with wall-paper, even including the floors and ceilings.

Now it is readily conceivable that 1. The proper wooden wall of any apartment may be so reduced in thickness as to hardly merit the name. 2. The wall may be omitted altogether at some point, leaving to the two layers of paper. 3. A fold of the lining paper may hang within some apartment. 4. Between the two layers of this fold a second fold of the covering paper may be interposed. 5. Instead of a complete fold of the covering paper, there may be supported in the fold of lining paper some looped strings or fringes, connected primarily with the covering layer.

Again, while the fold of lining paper is really projected into the apartment, the fold of the other, or its strings and fringes, being covered by the former, are not really within the apartment.

The lecturer then applied these transformations of a familiar structure to the explanation and interpretation of the structure of the brain, illustrating his remarks by a series of blackboard diagrams.

The question of nomenclature would be more fully dealt with in the closing lecture, but a brief reference to the subject seemed advisable at this point. Dr. Wilder pointed out that the unfamiliar names of the numerous encephalic parts formed a serious obstacle to the beginner. With students, therefore, few special names should be introduced at the outset. Moreover, the general terms should suggest familiar objects, as, for example, floor, roof, sides, lining, sheath, pipe, etc. On the present occasion, however, there was no objection to the immediate use of technical terms.

Since several of the latter are based upon the names adopted for the several encephalic segments, it may be well to say a word respecting them. The recognition of segmental constitution of the brain commits no one to the acceptance of any particular number of segments. But with regard to one segment there seems to be little or no difference of opinion. From the middle cerebral vesicle of the embryo is developed the region which is to prominent in the early stages of development. Its floor forms at least part of the crura cerebri; its roof shows the elevations known as lobi optici, corpora quadrigemina, corpora bigemina, nates excorticata, etc., and its cavity is designated as aqueductus Sylvii, or tertio ad quartum ventriculium. Von Baer called it mittelthirn, i.e., midbrain, or mesencephalon, which I have shortened to mesen.

The determination of the number of additional segments involves many considerations, and any view of the question must be tentative for the present. I have provisionally adopted the view, recognizing a segment for each of the five principal masses, which named in the order from the myelon, are commonly known as medulla, cerebellum, lobi optici, thalami, and hemisphaera cerebrals or cerebrum. The abbreviations used by Wilder for the names of the five encephalic segments are the following: Metencephalon, mesencephalon, diencephalon, and prosencephalon.

The cavities will be called celia. The cavities of the several segments would, therefore, be named as follows: Metacephalan, epencephalon, mesencephalon, diencephalon, and prosencephalon. The shorter and simpler English form would be:—mesencephalon, diencephalon, etc. In like manner we have metadialata, etc., and metaplexus, diaplexus, etc.

In the brain of the adult mammal the cavities are small, especially those of the epen and prosencephalon; but in the fetus, even of man, and at a stage considerably later than that of the life of the epencephalon, the prosencephalon is comparatively large, and Tiedemann characterizes the prosencephalon as a "vast and spacious cavity."

An encephalic cavity (coenia), like a mass of proto-
plasma, may partially subdivide (segment), may protrude symmetrically (bud), or be irregularly prolonged (cornu). The walls (paretes) may be thickened (hypertrophied) regularly or irregularly, and even to the extent of nearly or quite obliterating the cavity. Between the lateral walls may be developed bands of transverse fibres (commissures), either: First, In the pre-existing wall (post-commissura, commissura habenarum, and praocommissura); second, under the floor (pons); third, Between the opposed lateral walls directly through the ceolium (medio-commissura); fourth, between the contiguous walls of two adjoining masses (callosum and commissura fornices). The paretes may be corrugated so as to form ental elevations (hypocampae, calcar), with corresponding depressions (fissura hippocampae, fissura calcarina), or without corrugation of the entire walls there may be formed superficial ridges (gyri) and furrows (fissurae). Again, the walls may be thinned (atrophy) or disappear, so as to leave at a given point only the lining membrane (endyma), and the vascular sheath (pia), constituting a tela.

Further, along a line of atrophy of the proper wall a fold of pia, or a vascular loop therefrom, may push before it the endyma, and thus project apparently into the cavity as a pleura of the temporal lobe, but even never, neither the pia nor its vessels are in the endymal cavity in any other sense than the kidneys or the intestines are within the cavity of the peritoneum. One segment may also be inordinately developed, so as to overlap others in one or more directions. And its floor may become intimately connected with the roof of a segment so covered. Finally, the entire brain may be bent upon itself (cerebral flexure) or an elongated protrusion (cornu) may be bent (postcornu), or even bent and twisted also (medicorhaphy).

The apposed surface areas of the hemispheres are united by a new formation, the callosum. As a whole, the callosum is surrounded by the commissura fornices, the caudal ends of the two are eventually, if not primarily, continuous at the splenium. That part of each hemisphere wall which is thus interpreted between the callosum and the commissura fornices becomes (or remains) thinner than the rest, in man at least, and the two delicate laminae thus formed constitute the septum lucidum; each lamina is a semi-septum, and the space between them is the pseudocella or "fifth ventricle."

Original Articles.

THE PREVENTION AND TREATMENT OF Puerperal Fever.\(^1\)

BY FORDYCE BARKER, M.D., LL.D.,
NEW YORK.

During the five years which he had had the honor to occupy this chair he had never before seen a meeting of this Academy so enbraced by the charm of eloquence, the fascination of rhetoric, the glow of conviction, and the air of one who speaks by authority—an air which can never carry weight unless it has been before fairly and justly earned by good work—as on the evening of December 6th, when the paper was read on "The Prevention and Treatment of Puerperal Fever."

Its authoritative tone, its earnestness and sincerity, its coloring of being based on experience and observation, instead of being unconsciously deduced from preconceived theory, gave the paper such a plausible air of scientific truth as must secure its acceptance without question by many minds whose belief rests on authority without examination of the data or analysis of argument. The more eminent the author of errors which may dangerously influence medical practice in matters of such vital importance as the saving of life of those who have just become mothers, the more striking the literary excellence, and the more admirable the artistic merits of a paper promulgating such errors, the more necessary it is that such errors should be boldly and promptly refuted. Any paper read before this Academy by one to whom all conceded a place among the most eminent in the department of the profession to which his life had been devoted, if allowed to pass without examination and discussion, would be accepted by great numbers in all parts of the country as a statement of the science and medical practice as enunciated by the most prominent men of the period.

All would agree that the paper was remarkable for its originality, in that some of its pathological doctrines and the practice inculcated for the prevention and treatment of puerperal fever had never been taught in any work on obstetrics, or by any writer of acknowledged repute. If it were not accepted by the common intelligence of the profession they would assuredly be found in the obstetrical works of the future.

As there were many others who would take part in this discussion, he would, in the most concise language consistent with clearness of statement, give his reasons for thinking that the whole tone and coloring of the paper was misleading and dangerous, a disease so rapidly fatal and so associated with septic infection. He would not "speak disrespectfully" of puerperal septicemia. He believed it to be one of the most dangerous incidents which may occur to women after childbirth, and he trusted that it would not be regarded as indelicate if he alluded to the fact that in a work on puerperal diseases, published more than ten years ago, a lecture devoted to the consideration of this subject in all its relations fills thirty-seven pages. He had yet found no reason to make any essential change of the views expressed in that lecture.

In the paper under discussion the author distinctly avows his belief, without any qualification, that "puerperal fever is puerperal septicemia," and that "it manifests itself by the appearance of miliaria, cellulitis, phlebitis, peritonitis, or lymphangitis, the essence of the disorder is a poison which is absorbed into the blood of the parturient woman through some solution of continuity." Not only the sentence quoted, but the whole tenor of the paper must convey to the unbiased mind the well-defined opinion of the author, that miliaria, phlebitis, peritonitis, and cellulitis are never seen

---

\(^1\) An abstract of a paper read before the New York Academy of Medicine, February 7, 1884, at the adjourned discussion of the paper on this subject by T. Gil- lard Thomas, M.D.
in the puerperal woman except as the result of an initial lesion, permits the absorption of a specific poison through the parturient canal, either from the atmosphere or from direct infection by doctors or nurses, from neglect or carelessness, or other agents brought in contact with the sexual organs.

The tendency to this pathological view has been rapidly growing within the past few years, as a result of the enthusiastic interest excited chiefly by the important investigations of our German coworkers, who have so zealously studied the character and effects of the microorganisms in puerperal women in hospitals. No one, as yet, has maintained that the process of parturition and the puerperal state exempt a woman from those causes which induce local inflammation in the non-puerperal, or will delay the process of parturition, and other attendant conditions besides the absorption of septic poison, may be the efficient cause of local inflammation; and he here stated his conviction that in private practice, when there is no epidemic influence, twenty cases of local inflammation, due to such causes, will be met with where one will be found due to septic absorption.

Dr. Barber was in entire accord with the author in his preliminary remarks as to the peculiarities in the system of puerperal women, and had expressed these views in the work alluded to. He supposed that all educated men now know that the blood of a pregnant woman is in a state of hyperesthesia, and that, as a rule, "her nervous system is in a plus state of sensitiveness and vitality, and instability, which are very controllable in the non-puerperal state produced to a remarkable degree here." But it is very evident that in certain points our opinions are wide apart. Dr. Thomas regards certain conditions, which always are found following normal labor and always occur in normal puerperal convalescence, as pathological, while which Dr. Barker believed to be present in all puerperal cases, and which were believed in the poisonous nature of the menstrual fluid.

Dr. Barker had supposed this superstition to be extinct until informed by a letter from his friend, Dr. Weir Mitchell, that he knew "old men who would not permit a woman to enter their wine-room, for fear that, if menstruating, it would injure their wines." He also informed him that "they frequently believed in the poisonous blood in their cheese cellars." Dr. Barker supposed the theory must be that menstrual bacteria will destroy the bouquet of the Roquefort cheese.

But on the evening of December 6, 1883, in this Academy of Medicine, he first heard the full evolution of this theory, as clearly enunciated. The lochia are described as an offscrap, the uterus should be opened and decaying animal tissues, which poisons freshly made unprotected wounds, and here Dr. Barker quoted:

"In every case of child-bearing the endometrium is thus encumbered, and freed by a process of exfoliation and sloughing; in every case the cervix, vaginal mucous membrane, periton, and vulva are, in varying degrees, lacerated; and in every case the offensive fluid, called lochia, poisons these freshly made, unprotected wounds."

Again the writer says: "Here we have a number of recent wounds constantly and unavoidably bathed with a fluid made up of dead and decaying tissue, animal tissue in a woman whose blood and nerve states are, with reference to septic disease, like flax prepared for the spark, and who is exhausted by pain, anxiety, loss of blood, and deprivation of sleep."

Other quotations might be given of a similar tenor, and the prophylactic measures, which he asserts "should be adopted in all midwifery cases, whether they occur in hospital or in private practice," are based mainly on this theory.

Can it be true that the process necessary for the birth of the human race is always attended with the development of a deadly poison whose malignant effects must inevitably prevent the spontaneous and kindly healing of such little traumas as always result from the process, and that, therefore, it is the duty of the accused to take preventive measures of the character proposed? Does every parturient woman, in performing the function of maternity, like the scorpion, that carries in its tail an agent for suicide, if death is threatened by fire, physiologically generate an equally fatal poison in a corresponding locality, which the obstetrician must guard against by means that are most inconvenient, alarming, and not altogether free from danger?

He did not intend now to examine the question, which he had before discussed very thoroughly, and his views had long been published, whether there be not a distinct disease, most appropriately denominated puerperal fever, when, if there be any septicemia, it must be a consequence of a primary disease, and not a cause. Nearly a hundred years ago the eminent obstetrician of London, who succeeded Denman, Dr. John Clarke, wrote as follows in regard to puerperal fever: "Unfortunately, the uniformity of the disease was assumed, and each author erected his own experience into a standard, by which to judge of the descriptions and the practice of others."

All we know of any disease is derived from the study of its etiology, its clinical phenomena, and its anatomical lesions. The epidemic disease to which he had just referred differs in all characteristic points from what is known as septicemia. It differs in its origin, its modes of attack, its symptoms, and its anatomical lesions. The symptoms are frequently manifest a day or two before or even after childbirth; in septicemia, they are rarely observed before or during labor, except when the fetus is putrid. The former disease, puerperal fever, originates from epidemic causes, and from contagion and infection; the latter, from nosocomial malaria, from autogenic septicemia, and from postpartum infection.

The former disease is not the sequel of childbirth, but after childbirth is exposed to the danger of receiving the poison which produces septicemia in larger doses than when she has retained in her uterus a portion of putrid, decomposed placenta? Yet he did not believe there was a single person who had had considerable obstetric practice for twenty years who had not had more than one case of puerperal fever, and that the diseases are identical, for there is abundant evidence that, while these causes are always requisite for the development of surgical septicemia, puerperal fever may be a very epidemic when these causes are wholly wanting.

In the early months of 1873 puerperal fever prevailed in the best parts of the city, and in that class of society possessed of abundant means and living under as good sanitary conditions as are possible in any large city, to a degree and extent here unknown for the previous twenty-five years. The deaths from this disease in the hospitals and in the wards of the city where the poor are aggregated were much less than in many former years. In the residential wards of the city, in which are the residences of a great proportion of those of wealth, and few of the class of dwellings known as tenement-houses, with a population of 367,046, there were 80 deaths from puerperal fever, while in the remaining wards of the city, with a population of 605,745,
there were but 63 deaths. In other words, he might say that during this period, in those wards of the city where the causes of septicemia must have existed in the greatest abundance, the mortality was nearly one-third less from puerperal fever, in proportion to the population, than in the best parts of the city, where these causes of septicemia could have existed only in a very limited degree.

From all these considerations, he thought that if all the knowledge of this disease be derived from authors who have studied it in hospitals exclusively, it will be limited and one-sided, and the deductions, both as to its pathology and treatment, must, in many instances, be erroneous and false. Without further details, he would content himself by expressing an opinion which will surprise many who have been carried along by the popular wave of the septic theory, as the initial cause of most of the puerperal diseases. His conviction was strong, based partly on individual experience, but chiefly on a careful study of the clinical midwifery reports of private practice and all the literature of the subject in his possession—and this was very full as regards the English and French languages—that outside of hospitals less than two per cent. of the puerperal diseases, and not half of one per cent. of the deaths after childbirth were due to septicemia.

There are no statistics of private practice which demonstrate the error of this opinion. The belief of the septiciemists that dangers threaten when every woman who has delivered a child has what is called a puerperal fever is wholly based on theory. In support of the opinion just expressed, he did not wish to summon any higher authority, even if it were possible to do so, than the writer of the paper now under discussion, and from which he made the following quotations:

"And yet what are the usual results? Recovery, uniform. I might say universally, unless some unusual occurrence manifests itself to prevent this happy consummation. Theorizing about the matter, one would suppose that the mortality resulting from such a state of things must be excessive."

"And yet the facts are these: only about one or two in every one hundred parturient women ordinarily die, when properly cared for during labor, even in public hospitals."

With reference to "the prophylactic measures which should be adopted in all midwifery cases, whether they occur in hospital or in private practice," as the author of a well-known work avows: "if she who is about to bring forth must be treated as if she were about to go through the perils of a capital operation;" if all those preparations, so definitely enumerated, which gynaecological surgeons insist upon previous to an ovariotomy or a laparotomy, are necessary in ordinary labors; if the danger from child-bearing be so great that a wise and prudent obstetrician is justified in subjecting his patient to the hazardous depression of intense anxiety and fearful doubt as to results, and in surrounding her with the vivid apprehension of her family, instead of stimulating and cheering her with the great happiness of maternity and the hope of increased interest and love from her husband; if, all, or even a considerable part of the details mentioned are necessary, it must be impossible for thousands of lives which are now lost, and to spare "thousands of desolate households the sorrow of losing their female heads"—then it seemed to him evident that the State should make child-bearing a penal offence for all those families who do not have a sufficient annual income to make it possible to carry out all these requirements. Such a law could only be made effective, by giving the facts of the situation which appeared in The Medical Record of January 19th over the signature of Seth Hill, Stepney, Conn.

The description given of puerperal fever, true as it may be, in its outlines, of the septicemia which gynaecological surgeons are so often forced to encounter, he thought would strike obstetricians familiar with the disease in the lying-in chamber as the ideal picture of a poet, differing as much from the scientific description of trained clinical observation as the pictures of natural scenery by a Byron or a George Sand would differ from a scientific description of a mountain or a lake by Humboldt.

As to diagnosis, he could not regard the symptoms mentioned, even in their totality, as a proof of septicemia, as all of them are to be found in other puerperal affections, when there is no evidence of septic absorption, unless with the author it be assumed that all puerperal disturbances are due to this cause alone.

Dr. Barker then expressed his convictions by giving a few general propositions:

1. That puerperal fever, as met in private practice, we have to treat the consequences of some form of blood-poisoning. This may or may not be septic poisoning. In private practice, he thought it generally due to some occult, possibly atmospheric, epidemic influence; in hospital patients, nosocomial malaria, often associated with septic poisoning.

No treatment which interrupts the normal physiological processes—such as the retrograde metamorphosis of inflammation, the fatty transformation of the component fibres of the uterus, or the cicatrization of its internal surface by the exudation of organized lymph, and the development of a new layer of mucous membrane, or the healing of traumatic lesions—can be justified, unless positive evidence, now well understood in science, demonstrate their necessity.

Antiseptic injections, both vaginal and intra-uterine, are of great service when the indications for their use are clearly shown by local signs of general symptoms, but they cannot be recommended with safety as a routine practice on theoretical grounds, as, for obvious reasons, they may be most detrimental in retarding the cicatrization of lesions and the other processes of normal convalescence, and are otherwise sometimes dangerous.

With reference to refrigeration as a means of reducing fever in puerperal diseases. He had no question that it may be useful in some cases, but his own experience in this method of treatment has not been favorable. Many years ago he tried it in several cases in Bellevue Hospital, but he soon gave it up, as the results were less satisfactory than where other plans of treatment were pursued. Cold will effectively and usefully reduce the temperature in active inflammations and acute fevers, but in adynamic diseases and in hectic fever this must be attended with a rapid waste of tissue more dangerous than the pyrexia.

Dr. Barker then asked permission to refer to a matter outside of the question of the prevention and treatment of puerperal fever, but in behalf of the "truth of history." He asked any who might have felt sufficient interest to turn to the 320th page of his work on "Puerperal Diseases," where they would find on that and the following pages the subject of intra-uterine injections fully discussed. Instruments for their administration, which had been devised more than fifteen years ago, were shown to the class, and explicit directions were given as to the methods and indications for these injections, differing in no essential from those heard in this hall on the 6th of December. The lecture was delivered in the amphitheatre of Bellevue Hospital, in February, 1869, and the work in which it is printed was published in January, 1874. Then it may interest some to look at page 85 of volume iv. of the "Transactions of the American Gynaecological Society," and read the papers by Dr. Edward W. Jenks, of Chicago, and Dr. James R. Chadwick, of Boston, on intra-uterine injections, and the discussion which followed.

In conclusion, he added that his creed to-day is fully avowed on page 476 of the book to which he had before referred, and, unless in the future he learned new facts and new arguments to change his faith, he should, die impenitent."

### Additional Notes

- The table includes cases categorized by temperature range and duration, along with corresponding treatment and miscellaneous notes.
- The table is a continuation from a previous section, indicating an ongoing analysis of medical cases.
- The data is presented in a tabular format, with columns for duration, treatment, and miscellaneous notes.
The slight discrepancies in the number of cases employed in estimating the total duration of the various items, in the preceding tables, when occurring with the same temperature, and under the same treatment, are due to the fact that one or other of the items were omitted in the histories of the cases recorded in the case books of the hospital; this occurred, however, in but very few instances.

The preceding tables include 271 cases of cure. Of these—

Salicylic acid alone was employed in 113 cases.
Rochelle salt alone in 23 44
Potassic iodide alone in 14 44
Pot. iodide and colch. alone in 7 44
Sal. acid and pot. iod. and colch. in 18 44
Atropia, 1/16 gr. t.i.d., hypoder. in 8 44
Miscellaneous remedies in 66 44

Total 271 44

Comparing the averages obtained from the preceding table there results the following résumé:

**TABLE N.**

</tbody>
</table>

The average duration of the joint symptoms before admission to the hospital is included in these tables, because this item considerably influences the results of treatment; a subacute case of considerable duration before treatment was begun, being notably much more difficult to cure and obstinate than a recent and acute case.

The average duration of the stay in the hospital is given, because some English observers claim that although salicylic acid may diminish the duration of the acute joint symptoms, and of the pyrexia, that the actual length of time before the patient is fully restored, and is fit to be discharged from the hospital, is no less than when other remedies are employed.

In calculating the length of time during which the patient remained in the hospital, in a few cases in which, after the patient was completely well, he or she was retained in the employment of the hospital, such additional time after complete restoration has not been counted.

In the treatment by salicylic acid, and by iodide of potassium with wine of colchicum successively, the former was used at the commencement of treatment and replaced by the latter after a time, especially when the disease improved slowly, and where it showed any tendency to become subacute or chronic.

Under the treatment by iodide of potassium, and by this drug with colchicum, no average duration of pyrexia is given, since in only one case treated by these remedies was there any elevation of temperature; these methods of treatment having been employed mostly in subacute and chronic cases, or when they showed a ten-
dency to lapse into these forms. This accounts also for the fact that the average duration of joint symptoms before entrance to hospital, under the subdivisions of these two methods of treatment, is great.

On consulting Table N, on the preceding page, containing a résumé of the average results, we find that although there is little difference in the average duration of joint symptoms after entrance to hospital, under all other methods of treatment (ranging between twenty-one and twenty-seven days), yet with the use of salicylic acid these symptoms lasted about one-half as long (twelve and a half days).

Again, in considering the duration of the pyrexia, we find that after the use of salicylic acid it was considerably less than when any other method of treatment was employed. An apparent contradiction to this statement exists in the fact that, under the head of treatment by salicylic acid and iodide of potassium with colchicum, used successively, the duration of the pyrexia is less than in the average of those cases in which salicylic acid was employed alone; but the credit of this short duration of elevation of temperature belongs to the salicylic acid and not to the iodide of potassium and wine of colchicum, since the former drug was used first, and in all cases for a longer period than the average duration of the pyrexia.

The average stay in the hospital was less, also, with treatment by salicylic acid than by any other treatment.

These facts would indicate an immense advantage in the employment of salicylic acid for the cure of rheumatism.

But an objection might be made to this statement, or rather a conclusion, and very properly too, that it is not fair to compare the results obtained by averaging the duration of the various items, in a large number of cases, without any regard to the severity of the disease; thus, we find, that while salicylic acid was employed, in most instances, in acute cases, and in a proportionately small number of subacute or chronic cases, the other remedies were employed in a much larger proportion of the latter variety of cases; and these, being undoubtedly more obstinate, a comparison of the results as per Table N, is not entirely proper or just.

To obviate this Table L is designed; here only cases of equal severity are compared; and whenever the number of cases under any subdivision is large enough, the showing of salicylic acid is always better than that of any other remedy. Even such comparisons may be objected to, as not being comparisons of cases of exactly the same severity, since the maximum temperature only is taken as a measure of their severity. Certainly the maximum temperature is no absolute guide to the severity of an attack of rheumatism, but it is a fair indication, and is the only one of the symptoms which can be expressed by figures, there being no way of comparing the degree of local manifestations, especially since pain is merely relative.

Unpleasant Effects Following the Administration of the Various Remedies Used in the Treatment of Rheumatism.

On consulting the following table (O), it will be seen that disagreeable effects followed the combined use of iodide of potassium and wine of colchicum in a greater percentage of cases than after the use of any of the other remedies.

Then next in frequency comes salicylic acid given in solution, while this same drug, given in capsules, caused disagreeable effects in comparatively few cases, only eight per cent., while in solution the percentage was 21.3, almost three times as great. This was due to the frequency with which nausea and vomiting were excited when the drug was given in solution.

### Table O.—Exhibiting proportion of cases in which there were "Iodism," "Salicylism," etc.—400 cases.

<table>
<thead>
<tr>
<th>Symptoms</th>

</tr>
</tbody>
</table>

Since the resulting disagreeable effects are greatly lessened by giving this drug in capsules, it becomes a matter of interest whether it is as efficacious in the cure of rheumatism, when given in solution, as it is when administered in capsules.

The following table (P) shows that there was little difference in the results of the administration of the drug, in solution and in capsules, respectively.

### Table P.—Relative efficacy of salicylic acid given in solution and in capsules.

### Complications of Rheumatism.

It has been impossible in these statistics to give tables showing the comparative liability to complications, especially those of the heart and pericardium, with different methods of treatment, since, as a rule, the cases had
their complications already developed at the time of entering the hospital. Especially is this true of the heart complications, in which the uncertainty is rendered still greater when the patients give a history of previous attacks of rheumatism.

Table Q gives the nature of the complications. Of the 400 cases there were 144 which were complicated; but these 144 complicated cases presented 204 separate lesions, since in many of the cases two or more valvular lesions of the heart existed, and in others there was, in the same case, both a cardiac and some other complication.

Hence, the first line in the succeeding table represents the number of complicated cases; and where two lesions complicate the same case the second one is put on the second line, so that the first and second lines together represent the number of complicating lesions.

</tbody>
</table>

Summary.
Cases of rheumatism with complications, first attack, 70 in 127 or 54.1 per cent.
Cases of rheumatism with complications, second or more attacks, 74 in 259 or 28.6 per cent.
Cases of rheumatism with complications, all attacks, 144 in 400 or 36 per cent.
In the 70 cases of complications with first attack, 63, or 90 per cent, were cardiac.
In the 24 cases of complications with second or more attack, 64, or 50 per cent, were cardiac.
In the 144 cases of complications with all attacks, 127, or 89 per cent, were cardiac.
In the 127 cases of rheumatism, first attack, 63, or 30 per cent, were complicated by heart lesions.
In the 259 cases of rheumatism, second or more attack, 64, or 25 per cent, were complicated by heart lesions.
In the 400 cases of rheumatism, all attacks, 127, or 31 per cent, were complicated by heart lesions.
In the 32 cases of separate complications, first attack, 56, or 64 per cent, were cardiac.
In the 110 cases of separate complications, second or more attack, 91, or 65 per cent, were cardiac.
In the 204 cases of separate complications, all attacks, 177, or 87 per cent, were cardiac.

Of the 204 cases of separate complications 177 were of the heart and pericardium. Of these 177 cases of separate complications there were—Valvular, 146; pericardial, 25; nerves, 6.

In these 146 cases of valvular murmurs, 124 were of sufficient distinctness to be located, and their relation to the sounds of the heart ascertained. Table R shows the relative frequency of these murmurs.

</tbody>
</table>

In the above table only cases of first attack have been considered, for the reason that, since most of the cardiac
complications were found to exist at the time when the patients entered the hospital, in those cases which had previously suffered from rheumatism it would be impossible to tell with which attack, and hence at what age the cardiac lesions had developed.

Even in the cases of first attack it is possible for the cardiac lesion to have existed previously, though the patient denied any previous attack of rheumatism; but this does not occur frequently enough to materially alter the results of Table T. From this table it is seen that the greatest proportionate development of cardiac lesions with first attacks of rheumatism is between the ages of ten and thirty years—in young persons. This is independent of the greater frequency of attacks of rheumatism in the young.

Table U shows the relation of liability to cardiac complications to the severity of the attack, as indicated by the maximum temperature attained.

**Table U.**—showing relative liability to cardiac complications with attacks of different severity.

</tbody>
</table>

In this, as in the preceding table, only cases of first attack of rheumatism have been considered, for the same reasons as those already given. The result of this table shows that while those cases, in which there was no rise of temperature, were most exempt, the degree of rise of temperature in the other cases seems to have influenced very little the liability to cardiac complications.

Relapses occurred in 43 cases (while in hospital). Percentage of cases in which relapses occurred while in hospital, 104 per cent. There were not a sufficient number of cases which remained in the hospital any length of time after being cured to furnish tables, showing the liability to relapses, with or after the various methods of treatment.

**Objectionable features of certain methods of prophylaxis against puerperal fever.**

By Simon Baruch, M.D., New York.

The importance of the recent papers, discussions, and editorial comments on the subject of the "Prevention and Treatment of Puerperal Fever" cannot be overestimated. It was a wise suggestion of Dr. Fordyce Barker, the President of the New York Academy of Medicine, to devote a second evening to the discussion of the most elaborate and authoritative paper of Dr. Thomas. The latter enumerated some propositions which are somewhat startling, and which, emanating from one of our most eminent obstetricians and clinical teachers, are destined to exercise a vast influence upon the practice of obstetricians. It is to be hoped that in the forthcoming discussion of this notable paper the most important features will not be overlooked as they were in the last discussion, immediately following the reading of the paper on December 6th, and that some authoritative support or opposition will be offered to the proposition that the process of parturition should in the future be made a more important event than it has been regarded in the past, and that she who is to bring forth will be treated as about to go through a capital operation.

As far as I am concerned, I am bound to confess that I was startled by this novel and important proposition from one to whom many of us are wont to look for guidance in our obstetric and gynecic difficulties, and I was still more surprised by the fact that the gentlemen who followed with remarks upon the paper tacitly accepted its opinion and teachings. I therefore, upon reading the report of this meeting of the Academy, wrote a "Letter against Prophylactic Injection after Normal Labor," in which I hastily sketched my reasons for opposing what I regarded the most objectionable feature of this and other previous papers on the subject, with a view to direct the attention of our obstetric teachers and practitioners to the possible dangers of universal acceptance of the practice of injecting every woman who is passing through a normal puerperal period after a normal labor. I called attention to the pernicious effect upon the younger members of the profession by which such a method of prophylaxis may be followed, and urged a careful reconsideration of the subject, in order "to stem the tide ere it be too late."

In the discussion of Dr. Garrigues' paper in the County Medical Society, and that of Dr. B. in the Obstetric Section of the Academy, I again offered my reasons for disapproval of these injections, and I was rejoiced to note in the Medical Record of January 5, 1884, a lengthy editorial upon "The Prevention and Treatment of Puerperal Fever," which sustained me in my active opposition to prophylactic injections after normal labors. As the Society reports, and especially the Laboratory editorial—which, by the way, is the only editorial comment upon this most vital topic which I have noticed, have clearly presented my views upon this subject, I will only briefly recapitulate them here, by stating that I "offered my unqualified condemnation of prophylactic injections after normal labor," because in my limited experience they have proved harmful, because they have been known to produce dangerous symptoms, because they interrupt the quiet tenor of recuperative processes, and lastly, because they are in direct contravention of the principles and practice of modern wound treatment. The able paper of Prof. Thomas has gone forth to the world and is now republished in various provincial medical journals as the teaching of a justly eminent authority. The weight of his name lends a decided import and enhances the influence which the skillful presentation and persuasive rhetoric of the author have naturally created.
As I have said on a former occasion, only a strong sense of duty would prompt me to dissent from the views of those for whom I am professionally the highest respect, and whose counsel I am in the habit of seeking whenever I require it; but actuated by the conviction that his teaching on the subject is fraught with danger, I should be recreant to my duty as a physician were I to stand idly by and permit these views to pass unchallenged. This was my reason for taking the initiative in proposing prophylactic injections. I had hoped that ere this others would have been induced to express their views untrammeled by prejudice and unaided by the weight of authority confronting them. But thus far I find myself feebly supported in the societies and entirely unsupported in the public prints, except by the valuable editorial in The Record of January 5, 1884.

Feeling the courage of my convictions on this point, I desire to offer additional points to strengthen a position which, as I have shown, is sustained not only by theoretical consideration but also by clinical evidence derived from the greatest lying-in institutions in Germany.

The terrible picture drawn by the report of the Berlin Committee on puerperal fever, is quoted with such telling effect in the paper of Professor Thomas, is, in my estimation, quite inapplicable to our country. If we may take New York City as an example (and it is well known that large cities present the greatest mortality from puerperal fevers), we are forced to the conclusion that the mortality from the dire malady is comparatively small.

I am indebted to the courtesy of Drs. Day and Nagle, of the Board of Health, for reports from which I gather the following valuable data.

Dr. Nagle "estimates" the number of "births not reported," in each annual report, as here indicated.

</table>

These exact statistical records of deaths and nearly exact records of births offer unimpeachable testimony to the fact that the percentage of deaths from puerperal fever, even when all allied affections which may be grouped under this common nomenclature are included, is very small, less than two-thirds of one per cent. One-half of this mortality, too, is noticed in tenement and cheap boarding-houses, where the elements for the development of puerperal fever are in full operation. When we take cognizance of the fact that the mortality is the outcome of cases which have as a rule not been subjected to antiseptic prophylaxis, and that the ratio of mortality compares favorably with the ratio in the average of the best lying-in hospitals in Germany, where every legitimate precaution to avoid sepsis is studiously taken, we are brought to the conclusion that the necessity for ac-

tive prophylaxis does not exist here to the extent which would be inferred from the report of the Berlin Committee on Puerperal Fever.

At all events, it must be confessed that we are not warranted in resorting to a method of prophylaxis, most of whose demands are impracticable, objectionable, not proven successful, and dangerous.

### First.

Among those parturients in whom the greatest liability to puerperal fever obtains, viz., the pauper and menstruation population, and among the indigent classes everywhere, the execution of prophylactic measures, especially of the injections, is utterly impossible. These people have not the means to obtain skillful nursing. That no ordinary nurse should be entrusted with such work is admitted by the advocates of these measures. Moreover, whether among the indigent or wealthy, the accomplishment of these measures is utterly impossible. The three per cent. solutions of carbolic acid, which have heretofore been so confidently trusted to effect the purpose, have been shown by Koch and others perfectly harmless to the spores of bacteria. A more striking illustration, however, of the impossibility of completely rendering the vagina aseptic, is afforded by the mechanical apparatus we have to the disposal of us all parts of the vagina. They may be readily comprehended when it is remembered that the numerous folds and clefts within the genital canal may hide within their recesses myriad of germs and spores, which could only be dislodged by actual contact of the germicide by means of swabbing and forcible distention, measures which are surely impracticable. If by the new method we obtain the most energetic scrubbing with brush and soap and germicide, and to the punctilious search for filth and germs under the finger-nails in order to render our hands aseptic, how much more necessary and imperative would become the unfolding of each ruga and fold and the gaping of each cleft of raw surface in the vagina and upon the cervix, if we are to execute what is called a true antisepsic cleansing? I maintain that the latter cannot be consummated and has never been accomplished.

### Second.

The entire practice of prophylaxis, based upon the idea that "the process of parturition should in future be made a more important event than it has been regarded in the past," and that it should be treated as about to go through a capital operation," is objectionable on account of the moral effect upon the parturient woman in particular, and all expectant mothers in general. Hitherto the prospective parturient has been cheered by her friends, who have assured her that parturition is a natural process which the physician is only called in to supervise and guide, and which almost invariably terminates in recovery. But when our women will see us order the removal of carpets, upholster, and window-hangings, and the sprinkling of floors, mattresses, beds, etc., with germicide solutions, when they will observe the busy injecting of the nurse, the idea will naturally arise in their minds that the doctor is extremely anxious, and that a natural process, which every woman has been taught to bear with fortitude and fairest prospects of recovery, is now regarded with solicitude and as fraught with danger which may be prevented only by energetic and formidable measures. Can any one doubt the result? Demoralization will surely ensue, and our women will approach this accouchement with fear and trepidation. The removal of curtains, portières, carpets, and upholstered furniture, those tasteful ornaments which a refined and cultivated woman deems as necessary to her comfort as her blank-ets and pillows, and which tend to the lying-in-chamber a charm which we unsentimental doctors even cannot resist, would be quite worse. We may safely say that "they must be dispensed with, if possible." It is always possible to dispense with these luxuries, but what will be the moral effect of this "change" in her surroundings upon a delicate and sensitive nature? Throughout all
her life a refined woman has been accustomed to the presence of the ornaments which her means and her tastes have provided; she has observed that her friends have been in the habit of adorning the chamber in which they were wont to pass the most eventful days of their lives, and she, too, has followed their example and has taken as much interest in the beauty of her curtains, the artistic elegance of her furniture, the rich designs of her draperies, as in the preparation of the trousseau of the expected visitor. Of these praises she must now be deprived. Her chambers of sorrow must be arranged as if she were within the precincts of a hospital, and when she emerges from the agonies of labor her eyes must be greeted by naked walls, unfurnished windows and bare floors for days and weeks to come; nothing to cheer her but the assurance that the doctor says it is necessary for her safety. And after she has submitted to all those agonies of body and mind which to a sensitive nature the act of labor must bring, she must needs be subjected to the frequent approaches of the nurse with syringe, rubber cloth, and all the horrid paraphernalia of an injection. The word alone strikes terror into the mind of a young woman of delicate sensibilities who has probably never been treated gynecologically.

These may be sentimental objections, but all physicians whose field of action lies among the better classes will appreciate their force, and be alive to the difficulty of enforcing so stringent a prophylaxis. If the necessity exists, it is the physician's duty to be stern and inflexible. But so long as we can spare our patients annoyance, discomfort, and the time necessary to get this method, it is my belief to refrain from inflicting these. I claim that the necessity does not exist under ordinary circumstances. When an epidemic of puerperal fever is prevailing, these extreme precautions may become necessary and would be justifiable, but even in this event it would be far better to screen a class of patients here referred to, to a distant locality free from those epidemic influences which at times seem to predispose to the development of puerperal fevers. True, it matters not how small the mortality may be, if by any measures it can be reduced, it is the physician's duty and highest prerogative to resort to them without stint of labor or trouble.

The results of a successful prophylactic hold out no promise of success in the prevention of puerperal fever. In a former paper (J. Y. Medical Journal, January 5, 1884) I have adverted to the fact that the best German obstetricians, among whom may be mentioned, Carl Brown, Spaeth, Breisky, Hegar, and Fehling, have abandoned the most prominent element, viz., the injection, in their cases; they only resort to it when indications arise, as fever, sepsis, etc., or after operative or protracted labors.

Since Semmelweis introduced strict cleanliness into the Vienna wards, and reduced the mortality from fifteen per cent. to two per cent., the importance of preventing the entrance of filth and disease-germs into the lying-in chamber has been recognized by all educated obstetricians. The solution of chlorine which Semmelweis used offered no greater security against actual disease-germs than is effected by the later resort to three per cent, carbolized solutions. It was, after all, his precise and stringent rules against appearing in the lying-in wards after passing through the post-mortem or dissecting rooms, and the enforcement of greater cleanliness among the attendants in contact with the parturient woman, which accomplished the wonderful results. The same practice has been followed by success since the time of Semmelweis, until the more recent energetic uterine and vaginal injections became the ultra-antiseptic practice. The latter was not long followed in Germany ere puerperal fever came to be one of the more conservative obstetricians to the fact that they had passed beyond the bounds of safety. The reaction which now exists in Germany against uterine pro-

phylactic injections and which is rapidly developing against vaginal prophylaxis also, bears witness to the fact that this method of prophylaxis has not been attended with success.

There have been no clinical nor statistical data brought to the elucidation of the question of the utility or success of prophylactic injections in the normal puerperal period. Neither hospital nor private records have been cited by our most prominent advocates of this treatment, while, on the other hand, the clinical evidence from the German and American hospitals and of the New York Maternity (Charity) Hospital have clearly demonstrated their inutility. In his paper on "Prevention of Puerperal Infection," Dr. Garrigues describes the sad condition of affairs in his institution. "It used to be rather an exception than the rule to see a perfectly normal lying-in period. I was myself on duty during the first three months (1883), in which 108 women were delivered, 11 of whom died. During the six months from October 1, 1882, to March 31, 1883, in which I was on duty last, 102 women were delivered, and 46 of these were seriously sick, 39, or almost one in five, of inflammatory puerperal diseases." Dr. Garrigues states in another portion of this paper that he has for the last eight years used cases of eclampsia, and has been treating the injection of iron, first week after delivery, etc. I quote Dr. Garrigues' experience as evidence of the inutility of these injections, although they were not cited by him for the same purpose. They tell their own tale and need no rhetorical adornment. While in surgery the antiseptic methods are followed by almost invariable success in the prevention of septic trouble, so that Volker and table are unknown in surgical wards, the same method has proved ineffectual in puerperal prophylaxis, because, as I have shown elsewhere, the traumatic surfaces after labor are not allowed to rest from antiseptic interference, while in the surgical treatment of wounds the strictest abstention from disturbance is practised. Again I plead for implicit obedience to the course adopted by modern surgeons. Only by this method will true prophylaxis be enforced.

Fourth.—The danger of prophylactic injections in the normal puerperal period has been pointed out by many authorities. Max Runge, Kehrer, Fischel of Breisky's clinic, and others have emphasized them. They have shown that fever, or secondary complication is caused by them, that collapse and shock have been produced, etc.

My own experience, although limited, warrants me in condemning this practice. During my residence in the South I never observed a case of true puerperal fever, although my obstetric practice was large, approximating nine hundred cases, with all the usual complications. Difficult labors, however, did not often come under my observation in negro practice, in which midwives usually officiate; hence my proportion of complicated labor cases was unusually large. Presuming that this immunity was due to a great extent to the better hygienic surroundings of my Southern patients, and realizing the different sanitary environment of my present clientele, I espoused readily the views impressed upon me by my friend Dr. Wyile and others, that antiseptic injections are necessary to prevent puerperal fever, etc., and adopted them as a routine practice. Having already recorded my experience elsewhere, I will refer to it here only to make this paper complete. I had the misfortune to observe six cases of fever, whose advent on the fifth, sixth, eighth, and ninth day was inexplicable to me on any other supposition than the idea that they were of septic origin and due to the tearing of the recently healed surfaces by the frequent injections. I could not resist the idea that septic material had been introduced by the nurses. All these cases occurred in healthy localities, five of the patients occupying houses in which no other families resided. A suspicion of my share in the case, I repeat, coincided with the case which resembled the severe type of relapsing sometimes ob-
served in the South, the diagnosis was made clear by reference to the differential symptoms, mentioned in a recent contribution on this subject.¹ No case of malarial fever of so severe a type had ever been observed by myself since my departure from the South, nor had I seen a case of malarial fever of any type in the vicinity or among the residents of the house occupied by the patient, recurrence of fever processes during the puerperal period, without other assignable cause, aroused my suspicion that the injections were the cause, and so soon as I carefully reasoned upon the various aspects of my cases, I desisted from the practice altogether. I doubt not that many fever processes which occur in the practice of the advocates of the injection method of labor, and which are said to result from causes, I, too, was unwilling to charge them to the injections until their too unpleasant repetition forced the conclusion upon me, and this will very probably be the experience of others. I have the satisfaction of having made a convert already of one of our ablest physicians, who opposed my views when they were first published. A recent case of fever, directly traceable to a vaginal injection by a most competent nurse, has shown him the error of his ways and caused him to reflect upon the subject. He has candidly acknowledged that he would no longer resort to prophylactic injections in normal puerperal conditions.

The experience of Dr. Garrigues may also be cited in support of the view that injections after labor are dangerous, producing or keeping up fever processes. Despite his most active antiseptic prophylaxis, this careful observer was forced to admit that a large and very serious percentage of puerperal fever processes continued, and that the mortality rate was still unsatisfactory. But so soon as he adopted the course of abstaining from the only injurious element of his prophylactic method, "the vaginal injection twice daily," a complete change occurred. "The effect of the described treatment has been wonderful; as if by magic all trouble disappeared. Ninety-seven women have been delivered since its introduction, and not only have none of them died, but there has scarcely been any disease among them."²

True, Dr. Garrigues, like all originators of an instrument or appliance, attributes his success in a great measure to his antiseptic pad. He claims that the latter obviates the necessity for preventive injections, which "become superfluous, and thus one great source of infection is avoided." I would not say aught in opposition to any of the washes or measures which will keep the disinfected nurse and syringe away from the genital canal, and if for no other reason than this most vital one I would advocate the adoption of Dr. Garrigues' antiseptic pad as a most useful and promising advance in prophylaxis. But in the discussion of the aspect of the question which is under consideration, viz., the danger of these injections, I refer with confidence to Dr. Garrigues' records before and since the adoption of the pad and abolition of preventive injections. Few judicial and discriminating obstetricians will fail to accept the marked success more as an evidence of the harmfulness of the injections in the first series of cases than as a demonstration of the value of the pad in the second series. Doubtless the extreme antiseptic cleanliness introduced by Dr. Garrigues, the guarding of the patient against meddlesome nurses and students recently from dissecting-rooms, the changing of rooms, the germicidal treatment of furniture and bedding (which, in a filthy hospital, is of paramount importance), all these admirable measures, so candidly and instructively described in his book, have added to his success. He has culled the better elements of antiseptic prophylaxis and he has rejected the pernicious injections; hence the gratifying results. Among the thousands of physicians in cities, towns, and rural districts who have a large obstetric practice, the view of the inutility and harmfulness of prophylactic injections in the normal puerperal condition, which I here endeavor to enforce, will need no argument. Their own experience, illustrating the rarity of puerperal fever, even when no preventive injections have been practised, will guard them against this practice.

As the less experienced members of the profession the latter will receive acceptance, because it comes from an authoritative source and because it has remained comparatively unchallenged. Upon these gentlemen I would urge a careful consideration of my views on this subject. In my humble opinion, prophylactic injections, either germicidal or antiseptic, in any cold water, or even in the puerperal period, will prove a veritable Trojan horse, admitting the enemy whom we are energetically striving to deny entrance into the precincts of the vagina, and thus letting loose the destructive elements among the torn and raw surfaces, which expose the open lymphatics. I would not, however, be understood to antagonize antiseptic prophylaxis and antiseptic treatment in ob strictures. As I have written on a former occasion, "the fourth, fifth, sixth, and even the seventh clauses of Dr. Thomas' 'Prophylactic Measures' are admirable, and cannot be too strongly insisted upon." But I would urge most earnestly that the removal of carpets, upholstery, furnishings of windows, etc., and the injections in normal puerperal conditions are objectionable, and may prove harmful for the reasons stated above.

¹ The Differential Diagnosis of Malarial Fever, by Simon Baruch, M.D. N.Y. Medical Record, January 5, 1884.
² Progress of Medical Science.
THE MEDICAL RECORD:

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY
WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, February 16, 1884.

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.

The discussion of Dr. Thomas' paper in the Academy on February 7th presents several points of interest which our readers will appreciate in connection with the editorial comments on the same subject in our number of January 5, 1884. The latter aimed to present a judicial résumé of the discussion in our several societies up to that date, and more especially to direct attention to several features of the subject which had not received the consideration to which their importance entitled them in the Academy, viz., the pathology and certain elements of the prophylaxis of puerperal fever.

On the subject of pathology Dr. Barker was not supported in his opposition to the septicemic theory of puerperal fever. He refrained from entering into an examination of this question, but referred to his published views in the work on "The Puerperal Diseases" for the arguments in favor of the "existence of a distinct disease, most appropriately denominated puerperal fever, when, if there be any septicæmia, it must be a consequence of a primary disease, and not a cause."

As the work belongs to the classical literature of the profession, it is well known that Dr. Barker presents a masterly and learned analysis of the various puerperal inflammatory affections, fortifying his position by a candid and thoroughly fair review of every author of note who has contributed to the knowledge of the subject. He recognizes a puerperal peritonitis, metritis, phlebitis, cel lulitis, septicæmia, and pyemia, but differentiates between these and a puerperal fever sui generis. In the treatment of this subject he differs from the almost universally accepted views of the present day, chiefly in his denial of the necessary connection of a septicæmic element in the etiology of these affections (except in the pure type of puerperal septicæmia which he delineates), and in the maintenance of the position that the puerperal septicæmia is mainly observed in hospitals, and forms but a very small proportion of the mortality in private practice. On the latter very important point no argument was advanced in rebuttal, and it would seem the proper scientific course to discuss this question from the standpoint of its able advocate. As the large preponderance of clinical material on this disease has hitherto been obtained almost exclusively from hospital records, may there not be an element of error on this point, which could be eliminated by reports from private practice, as that of the epidemic

of 1873, referred to by Dr. Barker, in which he studied ninety cases among "that class of society possessed of abundant means."

On the other hand, it cannot be denied that even among wealthy people the septic element may be introduced by careless doctors and nurses in so occult a manner as to escape detection. How many operating gynecologists will follow Dr. Thomas' praiseworthy example, of thoroughly disinfecting his entire person and changing every particle of clothing, after visiting a case of puerperal fever? And here Dr. Barker's remark may well be heeded: "Indeed, one can hardly understand how such a surgeon, who accepts the theory and believes in the necessity of such a prophylaxis and such treatment as is insisted upon in the paper under discussion, would ever dare to enter the room of a puerperal woman." Only the most thorough disinfection would justify such a surgeon.

There can be no question that the acceptance of the septicæmic theory of puerperal fever is a great stride in advance, inasmuch as the difficulties of diagnosis between the various affections now termed puerperal fever are swept away, without detrimental influence upon their therapeutics, and this point is amply illustrated by reference to Dr. Barker's lectures.

It is a noteworthy fact that fifteen years ago this clinical teacher strenuously insisted upon the antisepctic treatment which is now recognized as a great advance and which is almost universally adopted, in each and every one of the affections which are now grouped under the term "puerperal fever." A few quotations will perhaps be of interest, in view of the fact that so learned an authority as Dr. Thomas was "not aware that Dr. Barker had made use of intra-uterine injections, and described how they should be used, in the book referred to."

"Puerperal phlebitis.—Cleanliness having been strenuously insisted upon in the preceding page, the author says: "I have one suggestion to make, but I regard this as one of great importance. I refer to vaginal injections of warm water and carabolic acid (p. 299)."

"Puerperal metritis (p. 320).—"Throughout the whole treatment of puerperal metritis I regard vaginal injections as absolutely essential. Recently I have generally used the carabolic acid (formula given). If the lochial discharge be purulent, or particularly if the odor be offensive, the injections should be used four or five or six times a day, great care being taken to instruct the nurse how to use this without annoying the patient. If the discharge be positively fetid, we must not rely on vaginal injections alone, but must resort to their use within the cavity of the uterus. It is my belief that intra-uterine injections should be administered with the greatest care and always by the physician himself." The remainder of the chapter is devoted to the consideration of the methods of these injections, their dangers and the prevention of the latter, all of which have been so ably emphasized in Dr. Thomas' paper, and in the recent reports from Vienna and Prague.

"Puerperal peritonitis (p. 351).—"I regard vaginal injections (carabolic acid 5 j. to Oj. water) as very important in this as in many other of the puerperal diseases. If the lochia be very abundant and fetid the proportion of carabolic acid may be doubled or even quad"
ruped, and the injections should be used every six or eight hours."

_Puerperal septicemia_ (p. 409).—"Vaginal antiseptic injections should be thoroughly used two or three times a day. The necessity and propriety of intra-uterine injections should be carefully weighed and a decision made," etc.

_Puerperal fever_ (p. 504).—"If I have quite failed in giving clear expression to my views in former lectures, it will be useless for me now to point out to you the importance of antiseptic vaginal injections, or to tell you how and when intra-uterine injections are to be used."

It will be seen, therefore, that even in the pure form of puerperal fever Dr. Barker dwells with emphasis upon the necessity and value of antiseptic injections. The general treatment inculcated in all these puerperal diseases—consisting of measures to sustain the vital powers, to reduce inflammatory action, to allay pain by hypodermics of morphia—together with the local antiseptic measures and enforcement of strictest cleanliness, so clearly and strenuously insisted upon in these lectures, place Dr. Barker's therapeutics of fifteen years ago on the precise platform of the conservative obstetricians of the present day.

Whether septicemia be regarded as a primary or secondary element in puerperal fever matters little, if the treatment be the same. Perhaps the remarkably small mortality in New York City from puerperal fever is due to some extent to these early teachings of Dr. Barker, and presumably of other lecturers.

Dr. Lusk dwelt upon the influence of the round bacteria as a means of rapid diffusion of the poisons in certain cases of puerperal fever, and emphasized his belief that germicide injections would be of no avail after the tissues had been invaded by these enemies.

Dr. Mundé also avowed his opinion that much harm may, under these circumstances, be done by continuing the uterine injections.

The debate upon the subject of "Prevention of Puerperal Fever" brought out a decided difference of views. Dr. Barker's paper contained a vigorous arraignment of the active prophylaxis of the extreme septicimists. Invective, wit, and sarcasm levelled their batteries at the paper under discussion, creating an effect which not only left its impression upon the audience but which will serve to restrain many obstetricians from the adoption of extreme prophylactic measures.

The practical outcome of this part of the discussion is of immense import to the profession.

In our editorial remarks of January 5th, we took occasion to say, "How far shall the recommendations of the eloquent speaker at the Academy be adopted? Shall the general practitioner, everywhere, religiously obey the instructions given by Dr. Thomas in his prophylactic measures? This is the question at issue now." We endeavored to show that the most unpromising measure advocated by Drs. Thomas and Wylie was the administration of vaginal injections in the normal puerperal period of all cases in hospital and private practice. This measure had been vigorously opposed by Dr. Baruch, whose argument in the County Society and in the Obstetric Section of the Academy we quoted with approval. We endeavored to show that Dr. Baruch's arraignment of these unnecessary injections was amply justified.

And it is gratifying to us to learn that Dr. Barker made an able defence of our views on this important subject, and fortified his attack upon these prophylactic injections in the normal puerperium by a recital of the results of his large experience in private and hospital practice. In the remarks following the reading of his paper, he entertained the Academy with a rapid sketch of his experience with these injections, offering his reasons for their cautious and gradual abandonment, to which he was led by the observation of disturbances and interruptions during the first week of labor which he traced to them. Since September, 1882, he has rarely found it necessary to order these prophylactic injections, and since their entire abandonment the results have been more satisfactory. This testimony from one who has probably been among the first to advocate antiseptic injections, enforces the argument against prophylactic injections most effectively.

Dr. Mundé does not object to these injections, because he regards them as harmless, but he would condemn them most emphatically when applied within the uterus.

The closing argument of Dr. Thomas was a master-piece of polemic art, bristling with pleasant repartee, gentle irony, and good-humored thrusts (in response to Dr. Barker's effort), which elicited genuine applause, and altogether was one of the finest efforts of the eloquent speaker.

One by one, the objections to the prophylactic measures of his paper were examined by Dr. Thomas, and each was ably defended. The more extreme measures, involving much time and trouble and "subjecting the patient to the hazardous depression of intense anxiety and fearful doubts as to results, and surrounding her with the vivid apprehension of her family" (Barker), were justified by the argument that it is necessary in a matter of such vital importance to erect a high standard. Dr. Thomas did not attempt to defend his recommendation that "curtains, carpets, and upholstered furniture must be dispensed with as far as possible." We are reminded of this fact by a communication in another portion of this number, which appears to us to take a rather extreme view of the consequences of this prophylactic measure, whose recommendation was doubtless the offspring of a desire "always to give a high standard."

We are rejoiced to find that Dr. Thomas confesses to a change of heart on the subject of vaginal injections. He said that he felt a little weak in regard to their propriety in view of the evidence which had been brought out against them, and that he had lately omitted them, even in a case of artificial labor; that in laying down rules in the paper which he had presented he simply gave what seemed to him desirable, but he was willing at any time to discard any part of them as soon as they were shown to be rash or injudicious. This admission on the part of Dr. Thomas does him infinite credit, in that it evinces the true scientific spirit.

It is to be hoped that the arguments urged by the opponents of these injections, together with Dr. Barker's and Dr. Thomas' abandonment of them, after careful and conscientious experience, will serve to seal the fate of prophylactic injections, uterine or vaginal, after normal labors and in normal puerperal conditions.
HOSPITALS FOR INCURABLES.

Probably no thinking man will deny the truth of the statement which our genial Professor at the Breakfast Table long since elaborated in his own inimitable style, that "the learned professions have but recently emerged from a state of quasi-barbarism." Certainly no member of our own guild who is at all familiar with the trend of medical science can close his eyes to the mass of tradition which still clings to its skirts, or can fail to trace the baneful influence of many a time-wornfetch. Take, for example, the customary treatment of the infirm and hopelessly ill by the primitive savages here in America. They were simply taken to a retired place and left to die, if they escaped the other alternative of more heroic measures by means of a war-club. Now, candidly, although the analogy may at first sight seem a trifle strained, do we not neglect our great incurable class of patients in much the same way? Our treatment is virtually the same in kind, though, fortunately for the patient, the fashion of the day does not permit the same radical expression of enthusiasm in efforts to secure the "survival of the fittest." The effect of each policy is, however, uniform. The barbaric process of natural selection is scientifically preferable on the ground of being really more merciful to the patient and more immediately beneficial to the community, than the modern method.

But whatever be the causes which have combined to develop this surprising apathy in regard to the claims of a large proportion of suffering humanity, the unfortunate fact remains; the evil does exist. Those who are acquainted with the workings of our city hospitals need no words from us to tell them that there is not adequate and proper provision for our incurable cases. A very natural explanation immediately suggests itself in the case of all general hospitals which are not distinctively city institutions. Such hospitals must and should be conducted on the general plan of the greatest good to the greatest number. They cannot afford to extend the privileges of their wards indiscriminately, else their beds would soon be filled with a series of slow chronic cases, nine-tenths of whom could never be cured in the end, to the exclusion of a multitude of others to whom rapid relief could be offered. At a rough estimate, a dozen active, vigorous lives, intrinsically valuable to society, could be saved from death or disability in the same stretch of time consumed in the care of a single phthisis patient. Practically, for one reason or another, a trifling percentage of those who apply to any institution gain admittance. The rest either continue to drag out a dismal existence at home, or after more or less delay, bring up eventually at the city hospitals. Here, as elsewhere, whether from a sense of helplessness to afford relief, or from the absence of any active interest in a tedious and protracted case, they are put on a routine treatment and practically consigned to the supervision of the nurses. There are, to be sure, one or two small resorts for different classes of chronic invalids, but from obvious causes, these are entirely unavailable to the great mass of these unfortunate. For our part, we should vastly prefer the perfunctory swiftness of the aboriginal apotheosis to months of torture in a reeking tenement house, even with the only alternative civilization can offer, a pauper bed to die in at last. In common charity let there be a reform in this matter, or let us be humane enough to go back to starvation and the war-club.

We, who stand as sponsors for the public health, the sworn defenders of the sick, should make known this crying want with no uncertain voice. The responsibility plainly rests with us; and it is all the more urgent because the common instincts of humanity, the health of our children's children, and the claims of progressive science, unite in the appeal. Here and there a few noble-minded persons have attempted to meet the crisis, a notable example being the phthisis pavilion in connection with the University Hospital at Philadelphia. But as yet such encouraging instances are painfully and shamefully few. Public sentiment must be aroused, educated if necessary, and organized action inaugurated, to insure any definite and far-reaching results.

It has been suggested, in the way of conservation of energy here in New York, that the corporations of our several private institutions devise some general plan of organization, by which some one of them be constituted a chronic hospital, to which the rest might each contribute their share of patients. But there are many manifest objections to the expediency and practicability of such an experiment, chief of which is that such a hospital would require a suburban situation. A more feasible plan would be to obtain or build an institution as commodious as our principal asylums, within easy access of the city, yet retaining all the advantages of country air and surroundings. To this hospital any general hospital might transfer, either by a special ambulance or by ticket, their chronic and incurable patients. These institutions would thus be relieved of the burden of a variable number of cases, which constantly interfere with their proper hospital work, and proportionately limit their sphere of usefulness.

The benefits which would thus accrue to the poor patients themselves can hardly be estimated. Once in working order, such a hospital could with a little tact be made largely self-supporting, just as the army hospitals were to a great extent during the war, and as our asylums are at present. Light work in the open air would be therapeutically most important to many patients, while any in-door occupation that would keep the mind of the sufferer away from his bodily ills, would be of almost equal benefit. Advanced cancer cases, phthisis cases, and various forms of rheumatism and nervous disease, would naturally comprise the bulk of the inmates. The mere isolation of these from their social relations would only be in the direct line of our duty in respect to the prevention of disease, not only in its immediate, but hereditary, effects. Every one of these maladies has long been an opprobrium medicorum; who can tell what secrets might not be wrested from nature by a continuous and scientific study of them collectively. It would at least furnish a training-school, for which the profession has long shown its need. Our students are thrown into general practice with the crudest ideas of the practical management of the bewildering minutas of chronic cases.

The profession surely ought to take this matter more to heart. If the public are once impressed with the existence of this evil, the means to obviate it will not be
THE MEDICAL RECORD.

February 16, 1884.

long forthcoming. If we recollect rightly, this very subject was recently agitated by a number of our resident philanthropists. We most earnestly hope that the scheme is still only in abeyance, and has not proved abortive. It certainly ought not to fail from lack of support from the profession of medicine.

A NEW ANÆSTHETIC, BROMOFORM.

At a meeting of the Society of Physicians of Vienna Dr. Caj. Freiherr v. Horroch reported the results of some experiments with bromoform.

This bromoform was discovered by Löwig in 1832. It is prepared from the hydrate of bromal, by the addition of an alkali. It is an oily, colorless liquid with a pungent ethereal and aromatic odor and a sweetish taste. It boils at 151° C., is soluble in warm water and ether.

The physiological action of bromal was first tested by Dr. S. Steinauer (Virchow's Archiv, May 19, 1870), who found that it relieved pain and produced sleep. He attributed the action in part to the formation of bromoform. The action of bromoform itself was tested by Dr. Horroch (Allgemeine Medicin. Zeit., No. 3, 1884) in three series of experiments—first, by inhalation; second, by hypodermic injection; third, by giving it by the mouth.

In the inhalation experiments it was found that narcosis was easily produced in animals; the anesthesia being complete, and the excitement stage short and of a mild form. After recovering from the anesthesia the animals did not vomit and appeared well.

Hypodermic injections of one gramme of bromoform produced in large animals complete narcosis, lasting for an hour. During this time the temperature fell from 2° to 4° C.

The internal administration of bromoform in doses of one to one and one-half grammes produced sleep of several hours' duration.

The animals experimented upon were rabbits and cats, and the physiological effects upon these animals may be summed up as follows: The respiration is not notably affected. The pulse continues strong, regular, and of ordinary frequency. The peripheral ends of the vagus retain their irritability. The blood-pressure is diminished. Reflex excitability is entirely abolished, and irritation of the sciatic nerve failed to effect any changes in blood-pressure. In very profound narcosis the cortical brain-centres lost their irritability. The temperature of the animals sank in dogs 3.5° C., in rabbits about 4.5° C.

As to the value of bromoform as an anesthetic in surgery, four experiments had been made upon adults in Professor Albert's clinic. Three men had been successfully anesthetized. In these cases the excitement period had been short, the patients did not cry or struggle. The stomach was not disturbed. Children had been easily anesthetized.

On the other hand, bromoform, as an anesthetic, appeared to be milder than chloroform, and its vapors were somewhat irritating to the respiratory passages.

A PLEA FOR THE PHARMACOPEIA.

At the meeting of the New York State Medical Society Dr. Laurence Johnson made a very timely plea in favor of the greater use of the pharmaceutical preparations instead of those now so industriously forced upon the profession by irresponsible manufacturers. The very cogent reasons for urging this plea were set forth in our report of the meeting. Few physicians can fail to have been impressed of late years by the frequent visits of the agents of wholesale druggists, who politely leave their samples and their pamphlets with a request to be remembered. It has resulted that many doctors are recommending and using unofficial preparations, of which the character and composition are but vaguely known, and which vary with the druggist. If the practice continues there will be an increased difficulty in collecting experiences and arriving at definite clinical results. Manufacturers, also, often abuse the commendations of physicians and finally get their wares on general sale before the public.

We do not go so far as to discourage the use of official drugs or preparations legitimately made up in accordance with given formulæ by wholesale manufacturers. It is often of convenience to the physician to be supplied with these. There is no doubt that the plan pursued by some homeopaths of furnishing certain of the simpler medicines to patients is a profitable one. But it is the "compound syrups," the mystic elixirs, concentrated extracts, normal liquids, the "iædias," and "ines," which are becoming a source of demoralization and danger. We say, therefore, to our readers, stick to the Pharmacopœia and the drugs and preparations in it. If a doctor cannot succeed with these, he must fail anyway, or else become a quack.

THE GENERAL PRACTITIONER AND HIS STUDENT.

Some time ago we called attention to the fact that the general practitioner had a very heavy responsibility as regards the admission of fit persons to the ranks of his profession. We said then, what is very well known, that many were in the habit of taking any students who came along, without reference to previous education or fitness. For the doctor feels a little flattered at being able to say that he has students at his office. The result is that the general practitioner is directly responsible for a very considerable part of the load of unfit persons which now weighs upon the profession.

We have just received notice of an attempt at reform in this matter which we can heartily commend.

The Trumbull County Medical Society, of Ohio, at its meeting January 31st, passed a series of resolutions which provides for securing a preliminary examination of all proposed students of medicine who enter the offices of the members of the society.

A board of examiners is appointed before which all applicants for admission as students of medicine under the tuition of members of the society must pass a satisfactory examination in fourteen different subjects. The examination is in fine about the equivalent of that demanded for admission to a classical college.

The society further resolved that the time of study required by members of this society shall be five years, including lectures; and that "members of this society shall recommend their students to attend only such medical colleges as either require an examination for admission similar to the one required by this society, or make the full three years' graded course of study
obligatory for graduation therefrom, and otherwise endeavor to elevate the standard of medical education."

The society requests the Ohio State Society and the other county societies to adopt the above schedule.

We need hardly say that the action thus taken by the Trumbull County Society is most creditable, and will be widely approved. It may be found difficult to carry it out in its entirety at first, and perhaps some modifications of the plan may be needed. But it aims to throw some responsibility for the status of the profession upon the general practitioner, and thus will prove, we believe, wise and useful.

DOCTORS IN THE NORTHWEST.

The Chicago Tribune a short time ago published a lengthy and carefully prepared article upon medical education and medical practice in the Northwest. The statistics collected showed that the ratio of physicians to population was rather greater in this section than in the South, or in some parts of the East.

We give some of the more interesting facts that are presented.

First is a table showing the number of the population and of the medical men in Western States:

<table>
<thead>
<tr>
<th>State</th>
<th>Population</th>
<th>Doctors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Illinois</td>
<td>3,077,871</td>
<td>5,899</td>
</tr>
<tr>
<td>Indiana</td>
<td>1,978,301</td>
<td>4,993</td>
</tr>
<tr>
<td>Iowa</td>
<td>1,694,615</td>
<td>3,035</td>
</tr>
<tr>
<td>Kansas</td>
<td>950,096</td>
<td>1,964</td>
</tr>
<tr>
<td>Michigan</td>
<td>1,656,037</td>
<td>2,944</td>
</tr>
<tr>
<td>Minnesota</td>
<td>780,773</td>
<td>914</td>
</tr>
<tr>
<td>Nebraska</td>
<td>459,404</td>
<td>807</td>
</tr>
<tr>
<td>Nevada</td>
<td>46,466</td>
<td>134</td>
</tr>
<tr>
<td>Wisconsin</td>
<td>1,315,497</td>
<td>1,549</td>
</tr>
<tr>
<td>Dakota</td>
<td>135,177</td>
<td>218</td>
</tr>
<tr>
<td>Montana</td>
<td>39,159</td>
<td>77</td>
</tr>
<tr>
<td>Idaho</td>
<td>32,510</td>
<td>51</td>
</tr>
<tr>
<td>Wyoming</td>
<td>80,789</td>
<td>29</td>
</tr>
<tr>
<td>Colorado</td>
<td>194,397</td>
<td>570</td>
</tr>
<tr>
<td>Missouri</td>
<td>2,163,310</td>
<td>4,330</td>
</tr>
<tr>
<td>Totals</td>
<td>14,515,400</td>
<td>27,709</td>
</tr>
</tbody>
</table>

This table, says the Tribune, shows the proportion to be nearly one to 524—the like of which is not to be found within any equal area of the earth's surface. Since then the manufacture of doctors has proceeded at an increasing rate. The forty-two medical schools within these limits—leaving out of account students who attended Eastern colleges—have in the last three years granted the title of Doctor of Medicine to 5,364 persons, and there are from these same States 3,549 students in the various colleges of the country preparing for the practice of medicine. The figures show the country to be full of doctors. Indeed, every cross-roads where a grocery and blacksmith-shop are located has the shingle of a medical man in plain view.

In the cities the crowded state of the profession is still more marked, as the following table demonstrates:

<table>
<thead>
<tr>
<th>City</th>
<th>Population</th>
<th>Doctors</th>
<th>Out of</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chicago</td>
<td>503,185</td>
<td>918</td>
<td>548</td>
</tr>
<tr>
<td>Denver</td>
<td>25,609</td>
<td>137</td>
<td>260</td>
</tr>
<tr>
<td>Detroit</td>
<td>116,340</td>
<td>948</td>
<td>469</td>
</tr>
<tr>
<td>Indianapolis</td>
<td>68,358</td>
<td>264</td>
<td>859</td>
</tr>
<tr>
<td>Kansas City</td>
<td>55,745</td>
<td>167</td>
<td>333</td>
</tr>
<tr>
<td>Milwaukee</td>
<td>115,387</td>
<td>141</td>
<td>639</td>
</tr>
<tr>
<td>Minneapolis</td>
<td>45,387</td>
<td>121</td>
<td>587</td>
</tr>
<tr>
<td>St. Louis</td>
<td>390,518</td>
<td>738</td>
<td>475</td>
</tr>
<tr>
<td>St. Paul</td>
<td>41,473</td>
<td>75</td>
<td>553</td>
</tr>
</tbody>
</table>

The interesting statement is made that, of something over 90,000 physicians now in practice in the United States, only 8,300 are over 60 years of age. The vast majority are young and middle-aged men, who now control the bulk of the medical business.

As regards the colleges, there are, as is known, about 120 in the country. Of these only 22 require three or more courses, only 71 exact preliminary education or its pretense, and the length of courses is as follows:

<table>
<thead>
<tr>
<th>Weeks in Course</th>
<th>Regular</th>
<th>Homoeopathic</th>
</tr>
</thead>
<tbody>
<tr>
<td>34</td>
<td>6</td>

</tbody>
</table>

AN INTERESTING QUESTION IN A CHARGE OF MALPRACTICE.

In a case tried not very long since in Pennsylvania, where the issue was the liability for alleged malpractice in the treatment of a fracture of the lower third of the tibia and fibula followed by necrosis of the bone, a physician was called for the defense and asked to give his opinion as to whether the limb had been skilfully or unskilfully treated. He was also asked whether or not the limb was in as good a condition and the results were as good as the average run of cases of compound comminuted fracture of the leg that are treated in a skilful manner by skilful physicians, and whether in cases of such fracture followed by necrosis of the bone there is not almost always great deformity? All these questions were excluded by the trial judge, but on appeal they were sustained as proper and a new trial granted. The Court said: "The limb evidently deformed was shown to the jury, and the course of treatment to which it had been subjected was fully described by the witnesses. The inference sought to be drawn therefrom was that careless and unskilful treatment was the cause of the deformity. Hence it was vitally important for the defendants to satisfy the jury that such was not the case; that, on the contrary, the condition of the limb as exhibited to them was the result of the severe injury the plaintiff received, followed, as such injuries frequently are, by necrosis; that the limb was in as good condition as could ordinarily be expected in such a case, when properly treated by a skilful surgeon. In determining whether a disease or an injury has been treated with proper care and skill, courts and juries must depend mainly on the testimony of experts, and considerable latitude must necessarily be given in the examination of such witnesses and in propounding hypothetical questions for their opinion. The testimony proposed was competent and the witnesses should have been permitted to answer."
News of the Week.

Dr. G. Halstead Boyland has been obliged to resign the Chair of Surgery in the Baltimore Medical College on account of laryngeal trouble, and is spending the winter in Florida.

A New England Cremation Society was organized in Boston recently.

To Investigate the Utica Insane Asylum.—A resolution was introduced into the State Assembly last Monday, asking for an investigation of the recent death in the Utica Insane Asylum.

Organization of an International Sanitary League.—We have received from Dr. Van den Corput, editor of the Journal de Médecine et Chirurgie de Bruxelles, a copy of a proposition which he laid before the Colonial Medical Congress last summer. The author urges the formation in different countries of a permanent service of official information concerning the public health, and the creation of stations or bureaus for sanitary and hygienic information.

Dr. E. C. Seguin, of New York, has been elected Associate Member of the Société de Biologie de Paris.

The Weekly Medical Review has been chosen the organ of the St. Louis Medical Society. This is a compliment to our valued contemporary which it very well deserves.

The Real and Only Discoverer of the Germ of Cholera, according to the Nashville Journal of Medicine and Surgery, was Dr. W. D. Dorris, of Nashville, who, in 1851, "astonished his co-laborers by the announcement that this terrible disease was caused by a gnat." This gnat Dr. Dorris found always present in and about the victims of cholera. They were about one-twelfth "smaller than the ordinary night or black gnat, and had a body of a grayish color, with a tinge of red at the point of the wings." Our contemporary contends for the prior claim of Dr. Dorris with great seriousness.

Birth of Quadruplets.—Dr. G. H. Coburn, of Frederickton, New Brunswick, reports in the Canada Lancet the case of a multipara who, on December 18th, was delivered of four living children. One of them only lived two hours. The presentations were all "breech," and each child had a separate placenta. The mother convalesced well. The infants were small, each weighing about two and a half pounds, and they all died within the month.

The Garfield Hospital.—At a recent meeting of the incorporators, says the Philadelphia Reporter, it was announced that the total cost of the property, together with the sums thus far authorized to be expended for improvements, would amount to $40,500, and that a suit in connection with an estate, until lately pending in Philadelphia, had been decided in such a manner that the hospital had come into possession of the funds at issue. A board of directors was elected, including Dr. Samuel C. Busey, of Washington, and Dr. John S. Billings, of the army.

Every Man Having His Own Journal.—The Escolpiad is the title of a new quarterly, edited, published, and written entirely by Dr. B. W. Richardson.

The Small-fee System has been introduced into the out-patient department of Guy's Hospital. Patients are charged threepence for advice and medicine, or sixpence for a fortnight's treatment.

Annual Meeting of the Illinois State Board of Health.—The regular annual meeting was held on January 17 and 18, 1884. The secretary's report showed that during 1883 licenses to practise had been issued to 553 physicians. During the same time 163 applications had been refused, and 11 licenses had been revoked. Fifty-one midwives had been licensed. Three outbreaks of trichiniasis had occurred during the past quarter.

An Anatomy Bill for Illinois.—The medical colleges of Chicago have been suffering for want of "material," and a bill has been drawn up which aims to provide suitably for this emergency. It is claimed that the county commissioners, who have charge of distributing the unclaimed dead, wanted a bonus from the colleges.

Dr. Willard Parker.—We are glad to learn that Dr. Willard Parker is improving slowly.

The Moses Taylor Hospital, at Scranton, Pa., has received an additional bequest of $100,000 from Mr. and Mrs. Syne, the heirs of the estate. The late Mr. Taylor left $250,000 for the hospital. Thereupon the fertile-minded architects devised a plan for a hospital which will cost $350,000 or more to finish. After it is finished some $15,000 or $20,000 will be wanted to run it.

The Tax for the Support of the United States Marine Hospital Service.—Mr. Adams, of New York, introduced in the House of Representatives, last Tuesday, a petition signed by three thousand sailors and shipping men, asking for a repeal of the tax now collected from sailors for the support of marine hospitals, and that the institutions be maintained by the Government. A bill repealing the tax was introduced by Mr. Dorschimer last week and referred to the Committee on American Ship-building and Ship-owning Interests. A delegation of New York shipping merchants have already argued in its support before the committee.

Additional Chairs in the New York Post-Graduate Medical School.—Dr. William F. Fluhrer, Surgeon to Bellevue and Mount Sinai Hospitals has been appointed a Professorship of Clinical Surgery, dividing the chair with Professor J. L. Little; Dr. Bache McEvers Emmet, Assistant Surgeon at the Woman's Hospital has been appointed to an additional Professorship of Gynecology, the chair being occupied jointly by Professors Dawson, Skene, and Emmet.

Yellow Fever Notes.—Sanitary Inspector, D. M. Burgess U. S. Marine Hospital Service, reports: There have been 482 deaths from all causes at Havana during the month of January, 30 of these were from yellow fever, 6 from typhoid fever, 9 from pernicious fever, and 2 from diphtheria. Of those who died from yellow fever,
25 were among the merchant shipping and private individuals in the city, and the remaining 5 from the army and navy.

During the same month in 1883 there were only 14 deaths from yellow fever. The past year has been noted by absence from hurricanes and high winds at Havana.

Dr. Burgess continues disinfecting all ships bound to United States ports, which receive cargo or ballast at suspicious wharfs. At Rio de Janeiro, during the two weeks ending January 5th, there have been 14 deaths from yellow fever and 18 from smallpox.

An Attack upon the Management of Quarantine by the Marine Hospital Service was made by the Secretary of the National Board of Health before the House Committee on Public Health, at its last meeting, on which occasion Colonel Waring stated that Surgeon-General Hamilton had been "injudicious, unskilful, and unsuccessful in his quarantine work" and that "in his efforts to control public and official opinion he had been guilty of misrepresentation."

This wholesale charge, without specifying in what particular the Surgeon-General was at fault, is looked upon by the friends of both services as discreet and unworthy the representative of the Board, and will hardly be borne out by the facts, as Dr. Hamilton proposes to prove to the Committee at its next meeting. It is reported that the Executive Committee of the Board has attended every meeting of the Committee since its organization this session, while it is known that Surgeon-General Hamilton has not yet appeared before it. He will now have an opportunity to not only disprove the charges made, but show up the peculiar tactics of the Board in its quarantine work.

Cholera Notes.—During the two weeks ending December 15, 1883, there have been 54 deaths from cholera at Calcutta, and the Vice-Consul-General reports that "the general death-rate is moderate; cholera below the average and subsiding, season very healthy."
The reports from this section all come in punctured envelopes, showing that disinfection of the mails is still carried on.

THE SIMS MEMORIAL FUND.

To the Medical Profession and Others throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting testimonial than obituaries and eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations, and such as have had the direct advantage of his personal skill are among the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulse to the study of gynecological surgery in America.

It is believed that the medical profession everywhere, the vast number of women who owe their relief from suffering directly to him, and those who realize the benefit he first made possible, will gladly unite thus to honor the man through whose original and inventive genius such blessings have been conferred upon humanity.

At the suggestion of many friends, therefore, the subjoined committee has been organized, and it is proposed that a suitable monument be erected to his memory in the city of New York.

To this end the active co-operation of the medical profession and the many other friends of Dr. Sims throughout the world is respectfully solicited. Contributions of one dollar and upward may be forwarded to the journal which has been constituted the treasury of this fund—THE MEDICAL RECORD, New York.

February 16, 1884.] THE MEDICAL RECORD.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 7, 1884.

Fordyce Barker, M.D., L.L.D., President, in the Chair.

THE PREVENTION AND TREATMENT OF PUERPERAL FEVER.

Dr. T. Gailhard Thomas read a paper on the above subject on December 6, 1883, and the discussion was made the official order for the first stated meeting in February, to be opened by a paper by the President (see p. 170).

Dr. Barker, when the reading of the paper was concluded, said: The subject is now open for general discussion. So many of the Fellows of the Academy have signified their willingness to speak, and there are so many whom all will be anxious to hear, that I felt it to be a duty to limit my remarks on the paper just read to a very restricted time and to content myself with the enunciation of such general principles as I believe to be important truths without entering much into details. But there is one point which I hope will receive attention from the speakers who are to follow. Very early in my practice I began to direct the use of vaginal injections for the first week after labor, the antiseptic being Labarreque's solution. When I went on duty at Bellevue Hospital, now nearly thirty years since, this was made the invariable rule in the lying-in wards. Subsequently carbolic acid was substituted, and I give a formula for its proportions in the work on "Puerperal Disease." I have had partly injected its use in all my obstetric cases until the last two or three years past.

At the time of the meeting of the International Medical Congress in London, in 1881, I happened to sit at a dinner next to Dr. Thomas Keith, of Edinburgh, and had a very interesting conversation with him as to the use of antiseptics in ovariotomy. What he said was very suggestive and led to a good deal of subsequent reflection on my part as to the use of antiseptics in obstetrics. I recalled to mind the fact that often in my practice I had seen disturbances and interruptions of puerperal convalescence the first week after labor, and it occurred to me whether this might be due to the carbolic acid; and the following autumn I decreased the proportion of the solution in my doses one-half, and thought that my patients did better.

On further thinking of the subject, I said to myself: The carbolic acid, even in the larger proportions which I have formerly used, was not strong enough to destroy the micro-organisms; and is it not possible that nature has wisely so arranged as to furnish the best fluid for constantly flushing the raised and lacerated tissues in the much-malignated lochia? Are not absolute rest and freedom from disturbance of these tissues much more favorable to their restoration than any washes that can be used? Since that time I have considerably surprised nurses by directing that no injections should be used unless specially ordered.

Dr. A. A. Smith, who frequently visits my patients during the first puerperal week, when I have other engagements, informs me that this direction was given more than two years ago. Since September, 1883, it is only in a small proportion of my obstetrical cases that I have seen any reason for ordering vaginal injections. It is hardly necessary to say that absolute cleanliness is incompatible with them, and that not a spot of blood should ever be found on either the person, or her clothing, or her bedding.

We both can declare that since this time we have not had a single case, including instrumental cases, which during the puerperal period has given us any anxiety, or required more than one ordinary attendance of one daily visit for nine days. This may be only a happy coincidence, but it seems to me significant. I think most present will be glad to hear the views of others on this new departure.

Dr. W. M. Chamberlain said: I do not propose to enter into the general discussion of this subject, or of either paper which we have heard, but would like to notice some remarks made at the first meeting about the glass tube mentioned by Dr. Thomas and devised by me some years since for washing out the puerperal and septic uterus.

Dr. Thomas stated that he had found occasion to make some modifications in the instrument, namely, to bring the openings nearer together at the uterine end and to make an opening at the extreme end. The first of these I had long since done, and about the propriety of the second I still have some doubts.

Another gentleman criticised the tube as too large, and this suggests a point of much diagnostic value, as it seems to me, in determining in what cases intra-uterine injections should be given. Those cases should be omitted, or if employed, suspended. In every autopsy of a woman dying from puerperal septicism which I have seen the uterus has been found large, soft, and flaccid. And in all the cases during life which I have seen since I became critical on this point the same condition has existed. There are different grades of septical inflammation of the same tissue such as the mucous membranes of the genital passages, a little tear of the cervix, vagina, or perineum, and is marked by a gradual rise of temperature day by day, until, a week or more after delivery, the patient may come into a critical condition. This is the analogue of surgical fever, and is to be distinguished from the explosive form, which is generally seen in septicemia. In all these cases an attempt after delivery, ushered in by a sharp chill, lochial fetor, rapid rise of temperature, restlessness, anxiety, and prostration. When this exists, so far as I know, it always suspends the process of involution, the uterus becomes relaxed, the discharges accumulate in it, and are partially retained, and the uterus becomes a hot-bed where the spawn of microbes will fructify in profusion or the virus of putridity may ferment unrestrained. These are the cases, I believe, which require antiseptic uterine injections, and in these the os is so patulous and so soft that a large tube will pass readily, by its firmness will give a leverage which will lift the soft anterior lip, and leave beneath it a space for free exit of the injected fluid. In cases softened but not relaxed, the jet of fluid even as a large sound is safer than a small one in a soft urethra. While if the uterus be itself thus open there is reason to fear that its tubes and sinuses may also be patulous, and therefore liable to be entered or injected by a small tube, particularly if it be open at the end. The remarkable studies of Dr. Garrigues have shown us that the ordinary lochial discharge in a normal delivery is not noxious unless access of a ferment or a contagium from without be carefully excluded. I hope we may hear from him again on this point, and will leave him to give his account, which he will do much better than I. To the objection that in my tube, as originally made, the antiseptic fluid is evacuated in the vagina before it reaches the womb, I can only say that I had the best results with the original tube, and think it not probable that so large a calibre would be evacuated so rapidly by an orifice without the womb when that orifice was so small.

I repeat it, that I find no occasion for irrigating an uterus in which the process of involution is going on at or about the normal rate, for such an uterus does not contain the septic material to be washed away. Some, at least, of the cases in which the injections have seemed to do harm are to be ascribed to the failure to make this distinction.

Dr. W. T. Lusk thought that the Society was to be congratulated upon two such papers as that of Decem-
ber 6th and that of the evening, as, in many respects, in spite of the seeming antagonism between them, they really supplemented each other.

While it was his desire to confine his remarks to the local treatment of puerperal fever, yet he would venture to state his faith concerning the etiology of the disease, as in practice every man is governed by his theoretical views. He would not say that in his opinion surgical fever and puerperal fever are not only analogous, but are essentially one and the same process.

To maintain this definition it was necessary to bear certain facts in mind. Much confusion had been occasioned by the failure to classify as distinct from puerperal fever the action of certain extraneous poisons, such as the use of some of his opinion surgical fever and puerperal fever are not only analogous, but are essentially one and the same process.

Again, the differences in symptoms between surgical and puerperal fever are in a large measure due to differences in the anatomical condition. The introduction of poisons into the system through a clean cut stump necessarily would give rise to symptoms of a different nature from those produced by the same poison when introduced through a puerperal wound, where the serious infiltration of the tissues, the wide intercellular spaces, the direct action on the veins, and the ordinary machinery for the removal of the exudate, are all absent. The intercellular galls, all are active in conveying deleterious as well as the normal waste materials into the organism. Again, it should not be forgotten that in puerperal women a special danger exists in the proximity of the peritoneum to the seat of infection. But with differences of symptoms not explicable upon anatomical grounds, surgical and puerperal fever are linked together by the presence in both of the round bacteria. Both are of septic origin. Many arguments against the septic nature of puerperal fever are based upon a confusion of terms and the failure to recognize the modern distinction between putrid intoxication and septicemia proper.

A decomposing fluid containing rod-like bacteria only is characterized by the foulness of the odors it emits. When injected into the veins it produces symptoms of profound disturbances in the nervous and chylopoietic systems, the animal experimented upon becomes feverish, depressed, a stinking diarrhoea develops, but, unless the first injection be large or the injections frequently repeated, fatal results do not follow. In the case of the infectious, because the rod-like bacteria under no circumstances thrive and multiply in the human system, and this explains the fact that physicians have been known to go from the dissecting-room to the lying-in-room with their hands still stinking, and yet have not communicated puerperal fever. But the round bacteria, which thrive in putrefying fluids, but to which putrefaction is not absolutely essential, unlike the rod-like variety, under favorable conditions, which we term the predisposition of the patient, may penetrate the tissues, enter the lymphatics, and be distributed to the parenchymatous organs and to the serous cavities, and far away from the original site of the disease may form sturdy colonies which excite inflammation destructive in character or interfering with the performance of function. Or again, the round bacteria may be disseminated through the system by portions of thrombi dislodged from inflamed veins. In many cases, it is true, no such general dissemination of these fungi need ensue. If the septic micrococci are of feeble activity or meet with resistance from the invalid, it is possible for them to travel a short distance from the point of entry, and there to give up the combat, giving rise to circumscribed inflammations, such as cellulitis and local peritonitis.

With regard to prophylaxis, he thought too great a burden could be thrown upon the practitioner by insisting upon non-essential details. He should hardly expect great results from washing furniture, walls, and floors with antiseptic solutions. At least, in lying-in hospitals, where he had seen many epidemics of puerperal fever, there was a time when everything was washed and scrubbed with great vigor. No pictures adorned the walls, no carpets covered the floors, and carbolic acid was used without stint, but he had never observed the slightest influence upon the prevention or restraint of puerperal fever. The fumes of sulphuric acid had since been substituted with the best results, and he would strenuously recommend the modes of disinfection employed by the Health Board in all cases where there had previously been scarlatina, diphtheria, typhoid, or any other diarrheal disease. In this connection he asserted that a woman should never, if possible, be confined in the chamber adjoining the bath-room, as he believed that puerperal women were extremely sensitive to sewer-gas poisons.

In normal confinement the uterus contracted during the expulsion of the head and body of the child in such a way that no air found entrance into its cavity. There was no decomposition ever occurs normally in the interior cavity. In the vagina the conditions, on the contrary, are all favorable to decomposition. There the lochia stagnate, and there are found heat, air, and moisture, which favor putrefaction. Putrefaction of the uterine contents is not a primary, but a secondary condition, the changes beginning in the vagina and spreading upward after the injection of the infected placenta into the uterine cavity. This he considered an important point in practice, as in cases where labor had been normal, and there had been no needless interference with its progress, if the vagina was thoroughly cleansed it was rarely necessary to carry the injection into the uterine cavity.

In cases of difficult labor the contrary, where the hands or instruments had been introduced into the uterus, primary intra-uterine decomposition was rendered possible, and was then especially favored by lax uterine walls, and the presence of bits of retained placenta or decidua. In such cases the intra-uterine douche is often the direct means of saving patients' lives. It would, however, have been better if the uterus had been thoroughly disinfected, not after the symptoms of septic poisoning have developed, but immediately after labor.

The douche was then harmless, it stimulated the uterus to contract, and was a powerful means of preventing subsequent dangers. For his own part he preferred the fountain to the Davidson's syringe, but the choice was left to the operator. This form of douche was not the case of uterine infection were favorable results to be obtained from the douche. In cases where the round bacteria had been inoculated into a wound the disease rapidly progressed into the tissues beyond the original lesion, so that they were often advancing, a victorious army, far beyond the reach of the stream which was thrown into the uterus. Washing the arm the day after vaccination does not prevent the development of vaccinia. Washing the uterus after the pelvic tissues are invaded does prevent the development of puerperal septicemia. His advice, then, would be not to continue the uterine douche in cases where the results of the first injection furnished the evidence of its impotence.

The results of antisepsis, as understood by the speaker, had been most surprising in the lying-in asylums of Europe. In Vienna, where in his student days the mortality had been not far from five per cent, the reports now show one death from septicemia in two hundred. In Prague, during the last year, upon Professor Streng's division of eleven hundred cases, there was not one death from puerperal fever. But in these hospitals and everywhere, the indiscriminate use of uterine injections has invariably added to the mortality. With all the blessings from their use, with the indubitable fact that they have been the means of saving many lives, unless the indications for their employment are carefully
THE MEDICAL RECORD.

February 16, 1884.

restricted, it is to be borne in mind, that they are likewise capable of adding to the risks of the puerperal state, and of swelling the death-roll from puerperal causes.

Dr. H. T. Hanks: Mr. President and gentlemen, having listened to the very valuable paper of Dr. Thomas on the evening on which it was read by the author and having been invited by him and by our honored President to express my views upon this important subject, I have felt that it was due you all that I have to say, where so many will be glad to speak, should be in the fewest possible words that will fully convey my ideas. I have said that this paper is a valuable one, and this subject an important one. I do not say it advisedly. I believe this paper will have a most vital and lasting influence, and that in America, at least, the more intelligent physicians, many of these suggestions made and the course of treatment marked out by him are to become the accepted rules of the future on the treatment of this class of cases.

The profession of to-day, especially in this city, are read, except as papers which promised better results than those already in the press. It is not enough, says Dr. A. or Dr. B. to say that he has attended twenty-five hundred cases of labor, and lost but two patients from this fever among all this large number. If Dr. A. or Dr. B. have had, or remember to have had, but one case in every thousand, Dr. C., just across the street, who has equilibrium, says she shall, confesses to have had in every 150 of all his puerperal women, statistics from memory alone are uncertain. The disease is not found in the city so much more frequently than in the country, where you compare the numbers. I remember distinctly that in my five years' experience in country practice in Massachusetts one of my patients, two days after the birth of her child, confided to me she had a stop in her uterus. A month afterward she was seized with violent colic pains and soon vomited. An hour later she had a severe chill, followed by every symptom of septicemia and rapid general peritonitis, and she died on the fifth day. Dr. Godding, from a neighboring town, a venerable and able physician, who was called in consultation, concurred with me in pronouncing this a typical case of puerperal fever. We explained it then in this manner: The cold milk drank by the patient was not digested, and caused vomiting; straining at vomiting and the relaxation following allowed some extraneous poisonous matter to enter the open vessels of the womb; the chill and the fever followed in regular order, and death resulted. One other case came under my care during the five years of my country practice. This second one followed a difficult instrumental labor, where there was considerable laceration of the perineum and quite likely of the cervix, although at that time I had not been led to look after this lesion or expect a slow convalescence because of it. This was a case of puerperal septicemia, resulting in pelvic cellulitis and general peritonitis. She recovered, however. This made two cases and one death out of seventy-five confinements. I believe, from the fact of my being called frequently in the country at the present time to see cases of puerperal fever in consultation, that when numbers are actually considered and exact statistics are obtained, there will be found a much larger per cent. of deaths in country towns from this disease than the profession have been led to suppose.

But in this city I have been interested to get at the facts, and have obtained from the President of the Board of Health the statistics of deaths—not cases treated—from puerperal causes during the last four years, and I find there were 1,905 deaths in 1885, 2,165 in 1886, 265 in 1887, 246 in 1888, 265 in 1889. In 1885 the number was slightly less than in 1881, otherwise the increase from year to year could be explained by the increase of population. The startling fact is here manifest, that for the last four years in New York City, out of 120,418 puerperal women, there have been 1,905 deaths from puerperal fever, or one death in every 120 women who have borne children. One thousand and five deaths from among a class of patients who can be but poorly spared, who are the most important class, with one exception perhaps, of all that we are called upon to treat, is an alarming fact. I do not, therefore, speak at random when I state the profession at the present time are ready for any judicious change which promises better results for the future. And I thank Professor Thomas for an able contribution upon a subject which has interested us all of late, and which is of vastly more importance to the profession and to the world to-day than the subject of "How to Operate for Cystocele," or "How to Fasten the Pedicle after Ovariotomy," or "How I Stand and Believe in the Code Question."

Many of us who are frequently called to see these cases of puerperal fever, have been often led to ask ourselves, "How can we prevent and what can be done to cure these fearful cases?" I believe that I am sustained by a large number of the profession who are present this evening, if I say that "out of this one thousand and five deaths from puerperal fever in this city during the last four years one hundred and twenty-five cases of this disease, and when contracted, might have been cured, had these rules laid down by Professor Thomas been judiciously carried out. My object in speaking will have been accomplished if I can help to emphasize the importance of nearly all of these rules. I will speak first of the name. I believe that we have been too liberal in the diagnosis and approved or in his paper, "puerperal septicemia," and it may surprise you to know that to-day it is becoming more and more adopted by the profession. In 1880 there were reported in this city but 34 deaths from "puerperal septicemia," while in 1883 there were sixty-four. In 1880 there were reported, however, 49 cases of deaths from "puerperal fever," while in 1883 there were 143 from "puerperal metritis and metropenisitis." 64 from "puerperal septicemia," 5 from "puerperal pyelitis," 1 from puerperal pelvic cellulitis, 2 from "puerperal metritis," and 1 from "puerperal phlebitis."

Thus we see that these several names are used to-day to denote that puerperal disease was manifested in these various ways. In the light of present pathological teachings and intelligent diagnosis, one of the facts is that nearly all these several diseases have been caused, either directly or indirectly, by one and the same poison, taken into the circulation and resulting in these several organic changes.

For myself, I will say that during the last fifteen years in this city, where I have averaged sixty-five confinements a year, besides a large number in consultation, I have had two and sometimes three cases of puerperal fever, not always three deaths, from so-called puerperal fever. I have had no case that I could not satisfactorily explain as caused by absorption of the poison at a certain point of the genital tract.

But to come down to the practical points of the paper—the prophylactic measures to be adopted.

Rule 1.—Preparing the room by proper antisepsics and disinfectants. Always try and carry it out, always be certain you do enough, and that without alarming your patient.

Rule 2.—The nurse and physician thoroughly to disinfect themselves and their clothing. This rule cannot be carried out in 1881, 1882, 1883, 1884, or 1885, but it is useful, not so important as the first and second rules.

Rule 4.—Preparing nurses' and physician's hands, etc., before labor sets in. Absolutely necessary.
Rule 5.—Removing all clots of blood and tufts of placenta, and the giving of ergot in moderate doses for a week. Certainly important. The use of ergot in small doses can do no harm, but in full doses (one-half to one drachm doses) will cause an unnecessary amount of the laceration is extensive, but does not involve the sphincter ani, one deep suture, or two at most, should be introduced at once, the ends lightly twisted, not tightly, as we must expect swelling of the parts—then bent down over the anus or fastened with perforated shot. In no case should the long loops be allowed to remain directly protruding, to be constantly jarred by the antiseptic napkin, and a source of irritation and sometimes of great suffering. But, however, where the patient is greatly exhausted, the nurse, husband, and friends somewhat demoralized, the primary operation should be postponed. For we all know that even the secondary operation is often the cause of great fever, distress, and, occasionally, danger. Much more so may be the case if by antiseptic means the assistant finds the sphincter ani and into the rectum, by all means delay the operation until convalescence from the puerperal state has taken place, and you have your faithful assistants at command.

Rule 7.—Frequent antiseptic vaginal injections are necessary. Perhaps not in all cases; but if sickness follows where it has not been used, you will not cease to regret it. The use of the iodoform suppository. Placed near os externum may be useful in some cases. I should not insist upon this rule, since the distress and the labor attending their use must be considerable. The nurse cannot easily insert them, and the speculum ought never to be introduced for such purposes, excepting in extreme cases.

Rule 8.—Frequency of urinary vaginal injection. A good rule.

Rule 9.—Drawing the urine frequently with a clean catheter. An important rule.

Rule 10.—See personally that the nurse can do, and does do, her work well. Excellent and absolutely essential.

In the treatment of puerperal septicaemia I can only concur with every suggestion Dr. Thomas has made, and would add only one remedy to the list of therapeutic agents which he has recommended, and this is aromatic spirits of ammonia, given in one-half teaspoonful dose, diluted with brandy-and-water and generally given every two hours. Dr. Thomas' suggestion about the hypodermic needle is exceedingly timely.

In using the antiseptic vaginal injections I should suggest the use of a large bed-pan, like the one here shown, and thus avoid lifting the patient to the edge of the bed, for obvious reasons a dangerous procedure. The intrauterine injection should be used only when it is surely proved that there is infection in the uterine cavity. That in case the cervical canal will be partially open, and the small-sized Chamberlain glass tube should be passed in with the greatest gentleness, and the antiseptic fluid cautiously injected. I would again repeat that only when it is almost morally certain that the cause of the disturbance is within the uterine cavity should these injections be used. I should not advise the introduction of the Sims or Cusco speculum into the vagina, nor dilatation of the cervical canal, unless I were certain of finding large tufts of placenta in the cavity. The use of the rubber coil with cold water has served patients well after ovariotomy. I certainly should try it in puerperal cases whenever the occasion seems to demand. But this is a dangerous assistant if not watched. The diet of milk and animal broths is excellent.

The selection of a competent nurse and assistants necessary, if we are to carry out this plan, is an important matter. Some of the suggestions may seem unnecessary, a few, I believe, can be safely dispensed with. If the young physician who wishes to succeed in labor should find it impossible to secure a skillful antiseptic suppository every six hours, and he has no rubber coil, or that his patient has lost two drops of red blood from the vagina after the expulsion of the placenta, as one has lately claimed in this hall to be an abnormal and pathological condition, instead of "going out and hanging himself," or even following Horace Greeley's advice of going West, he should stop and reflect upon the fact that women have recovered from puerperal fever without the aid of either iodoform suppository or cold coil; and also that though his first patient may stain one or two napkins daily for a week with red blood, still she too may recover, and they both may in time laugh at the author of such a statement.

In conclusion I wish to give you the names of the four assistants who have always, when called upon, effectually aided me in the lying-in chamber. I have, of late, been accustomed to call upon my new patient and the nurse some weeks previous to the expected confinement, and telling them both of my desire to have present during delivery, and all through the puerperal period. These assistants find them themselves and respond to my request I respectfully withdraw from the case. If they consent, I go on and am satisfied with my labors, and expect perfect results. These four assistants are all important, and the first, second, and third, are of quite as much consequence as the fourth.

As I look back at my record of births I find that the worst of the disease is generally a constant has been the cause of a few deaths; the want of the second assistant the cause of no less than four deaths; the want of the third assistant the almost certain cause of three deaths, and weeks of sufferings for others, while the want of the fourth assistant has been equally disastrous. I give their names: "pure air," "absolute quiet," "judicious diet," "proper antiseptics."

Dr. P. F. Mound had listened with great pleasure and interest to the paper by Dr. Thomas, and also to the discussion this evening, but had felt at a loss to know what to say in case he should be called upon to speak. Since he first began to practise obstetrics, some eighteen years ago, he had seen a number of cases of general or puerperal septicemia. Although he had arrived at this conclusion, at the same time he wished to qualify the statement. Certainly, whenever he was called to a case in which he found an offensive discharge from the uterine cavity, attended by rise of temperature, preceded or not by a chill, he felt it his duty to wash out the cavity of the uterus. And if he failed to do so, he felt that he had failed in his duty to himself and to his patient. Again, however, he had seen cases in which, in the entire absence of evidence of infection of the uterus or of the perineum, he could not help feeling that the condition was something different from what we found in cases of septic infection. He could not help feeling that there were cases in which we had not the slightest difficulty to septicaemia. He was obliged to subscribe, in short, to the views of the honored president, that there were some forms of puerperal fever which we could not call puerperal septicemia. Regarding the etiology of puerperal fever, he had nothing to say, and yet the subject had of late been so much talked up that it seemed we would have to subscribe either to the view that puerperal fever was puerperal septicemia, or else that there was a pecu-
of one whose case was so poor as to make him resort to it; pain that I should see my old friend, our president, in such a strait. In a scientific discussion, more especially in a debate, which directly and immediately concerns the saving of human life, which at this very moment is being deplorably sacrificed among us, ridicule, elsewhere a powerful weapon, is the poorest and most pitiful of arguments. It is the resort of the weak, not of the strong; and as my adversary uses it just now I said to myself, he feels himself to be very weak, he totters upon his pedestal; 'tis pity that he should feel so, for otherwise that master pen, which so often in times past has enchanted us, would not to-night emit what carries pain to my heart and to the heart of every true friend of his in this assembly, evidences of instability and of infirmity which are so little characteristic of his real nature; otherwise I should not be able to recognize, as all others must do, the utter want of logic, the complete absence of argument, the total neglect of appeal to facts, and the very conspicuous presence of signs of wounded amour propre, which, like an unwholesome stream, meanders through his discourse.

I shall not detain you long. I have little to say, for Dr. Barker's attack calls for no rebuttal and demands no argument on my part. I said all that I had to say on December 6th, when the original fire-brand was thrown down, and unfortunately picked up by the wrong end by my excellent friend. There are, however, one or two points upon which I must touch, to avoid misrepresenta-

Dr. Barker declares the pathology which I have advocated to be unsustained by even the most recent researches of those who are our recognized guides; he appears to object to the fact that I have not stuck closely to the dicta of our text-books, and hugged to my soul the theories which they have promulgated. If I have so strayed, I strove to follow the advice of Dr. Billings, when he says, "Have something to say, say it, stop when you have said it." Had I had no opinions of my own to offer you, had I practiced in a large metropolis and in great hospitals taught me nothing during a period of thirty years, I should not have appeared before you. Let my adversary inform himself upon the recent views of pathologists upon this subject, and he will find that it is his views which are effete, not mine which are jeune.

As far as I can gather anything certain from his discursive paper, the pivotal idea of Dr. Barker's attack seems based upon the belief that I regard the lochial discharge as a poisonous fluid, which by absorption into the current of the blood produces septicemia. I need not tell you that no such absurd idea ever obtained foothold in my brain or enunciation from my tongue. If his idea be this, he has been guilty of very superficial reading of my paper, and should not so easily have concluded that I was affected by idiocy. Look at my essay, which is now in print, and you will see what you already appreciate must be the fact, that I stated merely that the lochial discharge was a material ready to take on those alterations which are effected by micro-organisms of bad character, which changing its nature render it poisonous to the abrased tissues. I believe that you will find that the pathology which I have there offered to you is abreast with the views of the advanced pathologists of Germany, France, and Great Britain. As to the pathology of my adversary, Dr. John Thorburn, of Manchester, England, very justly expresses concerning it, I think, the accepted view of the profession when, in a footnote to an article upon "Metria," which appears in the British Medical Journal for August 11, 1883, he says: "It would be inexcusable not to make allude to the admirable papers of Dr. Napiér, in the Obstetrical Journal for 1880, on "Puerperal Fever." He, along with Fordyce Barker, defends the old position of a specific puerperal fevers sui generis. The time limit imposed by our regulations allows no opportunity of consulting step by step such arguments as he adduces. I
can only say that his invaluable collection of facts produces in me an opinion diametrically opposed to his own.

My critic upbraids me with want of thoroughness and exemplifies, in detail with reference to my description of symptoms. I will merely say in answer to this that I intentionally assumed this style, as I was not preparing a lecture for a class of medical students, and my paper was distinctly announced to be upon "The Prevention and Treatment of Puerperal Septicemia," and upon nothing else. I can not but thank him for his kindness in comparing my style in this sketchy description to that of Byron and Humboldt (I believe that these are the authors with whom he compared it); but alas, as I recall the passage to which he alluded, I am pained to confess that the similarity of style does not strike me as forcibly as it does my partial friend.

Here let me draw the veil of pitying silence over the unfortunate allusion to the squib of Stepney and the relics of the Hotel de Cluny. We stand to-night upon ground consecrated to science by the dignified fathers of the New York Academy of Medicine who have now passed away; we stand face to face with the terrible mortality which marks puerperal fever at this very moment.

And now, gentlemen, a few words as to the prevention and treatment of puerperal fever, which is the only domestic subject before us for discussion this evening; the only theme which should not, at the very commencement of these exercises, have been rigidly ruled out as irreverent by our president.

Dr. Thomas then spoke of the methods which he had suggested for avoiding the occurrence of puerperal disease, to which I seemed to have taken exception as being impracticable. To carry out the first requirement, regarding the preparation of the lying-in room, it was only the work of two or three hours for a laboring woman. But in making rules, it was necessary always to give a high, and not a low, standard. He would admit that a woman might be confined in a dirty room and yet have a perfectly natural confinement; but he thought it did good to get the mind of the obstetrician into the proper channel, which was that of cleanliness, three times repeated.

Coming to the second rule, he thought this also quite practicable, and it was only this morning that he had bathed his hands, washed his hair and beard with a solution of boracic acid, and followed the rule laid down of having attended a case of puerperal septicemia yesterday. After going over the other rules, to which it would seem there could not possibly be any valid objection offered. Dr. Thomas spoke of the administration of ergot, which it had been his custom to do for some years, and with apparent benefit; and then of vaginal injections, regarding the propriety of which he must confess, in view of the evidence which had been brought out in the discussion, he felt a little weak. As Dr. Mundé had said, it was his usual habit to make vaginal injections, but he was willing to give it up at any time he became convinced that it was faulty. Only recently he omitted it in a case in which he was made to reflect that eighth month, and the woman did perfectly well. In laying down the rules in the paper which he had read he simply gave what was his practice, and what seemed to him to be desirable, but he was willing to discard any part of them as soon as they were shown to be rash or injurious. With regard to intra-uterine injections, he was, as stated in his paper, and in as plain and good English as he could command, utterly opposed to them except where there was good and sufficient cause, and he had stated as strongly as he could do the dangers which might attend the use of such injections. He was not aware that Dr. Barker had made use of them and described how they should be used in the book referred to, else he certainly knew him with more credit.

Dr. Thomas then quoted the statistics given by the speakers of the evening, and by others, going to show that puerperal fever was not of so infrequent occurrence as one might be led to suppose, and this was especially the case where antiseptic precautions were not observed, since December 6th he, himself, had seen as many as five cases of undoubted puerperal fever, and this was not above the usual number for an equal period of time. He then gave an instance going to show that statements made from memory by physicians, to the effect that out of a large practice for a great many years they had not had a single case of puerperal fever, were very unreliable. They meant to tell the truth, but their memory failed them.

Dr. Thomas closed his remarks by saying that he was not at all inclined to the rules which he had laid down; not at all. He was willing to alter them as soon as it was shown that they were objectionable.

The Academy then adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, January 23, 1884.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

Specimens for candidates were presented by Dr. Birdsell, Amidon, and Peabody.

DR. GEORGE R. ELLIOTT presented a specimen of NEURO-FIBROMA COMPLICATING SPINA BIFIDA.

It was accompanied by the following history: The child was first seen at the clinic of Dr. M. Josiah Roberts, at the Post-Graduate Medical School, April 10, 1883, about two months after birth, and presented at that time a tumor in the dorso-lumbar region. The tumor was oval in shape and measured three inches in its longer diameter, which corresponded with that of the spine, and two inches in its transverse diameter. It was distinctly fluctuating to the touch and covered by a membrane which in places was translucent. The base of the tumor was broad, there being nothing approaching a pedicle. Deep digital pressure showed the post-vertebral arches to be absent at the site of the swelling. There was no paralysis of the lower extremities, but double talipes varus existed. The anterior and posterior fontanelles were open.

There was also double internal strabismus of both eyes, most marked in the left member. I examined the eye with the ophthalmoscope and found evidence of a chronic circumscribed retinitis in the vicinity of the left macula lutea.

There were no marked cerebral symptoms present other than ocular, above cited. The child, however, showed lack of animation and was especially unobservant. By means of the sphynxoscope it was made apparent that communication existed between the cerebral ventricles and the sac of the spina bifida. The head gradually increased in size, the fontanelles becoming more widely dilated. Emaciation began from this date. At intervals of three or four weeks fluid was withdrawn from the sac, and pressure applied over the tumor. Under these treatments there was a slight diminution of the swelling, but no appreciable diminution of size. Emaciation steadily became more noticeable.

Early in October last, about 3½ of Morton's fluid was injected into the cavity of the sac after the withdrawal of some of its fluid contents. The child at once passed into a comatose condition and died three days afterward.

The parents of the child were both remarkably healthy, and the mother, a primipara, nineteen years of age, gave no history of any violence or maternal impression during utero-gestation which might have been factors in the production of the deficiencies above mentioned.

Autopsy.—Made twenty-four hours after death; body was extremely emaciated. The covering of the sac was thin and translucent in places, and in other parts considerably thickened, apparently the result of inflammatory exudation. The
thickening was especially marked in the entire circumferential part of the tumor, where there was a thick band of tissue grading into the sac covering the superficies of the tumor on the one hand, and into the healthy skin on the other.

The sac contained thirty cubic centimetres of turbid fluid, which, upon microscopic examination, was found to contain red and white blood cells and columnar epithelium. Chemical examination gave in addition the normal ingredients of cerebro-spinal fluid. The inner surface of the sac-wall appeared to the unaided eye like a smooth surface with nerve-fibres coursing over it. The base of the tumor rested upon the bodies and pedicles of the eleven and twelve dorsal and those of all the lumbar vertebrae. Lying upon the base of the tumor and projecting into its cavity was found an oval-shaped growth, the contour of which was identical with that of the tumor in question, but much smaller. At the cephalic end of the sac was an aggregation of nerve-fibres which immediately broke up, some of the fibres coursing around the growth at the base of the sac, traversing the sac wall throughout its entire extent, and perforating it at its caudal end at various points. Other fibres passed directly into the growth, in the substance of which they were lost.

Upon the same part of the wall of the sac, there was a large nerve-fibromata with the fibrous element largely predominating. (Microscopic slides showing it were submitted to the Society.) Careful dissection from above showed that the sac was made up largely of the original membranes of the cord, it being possible to separate the pia mater from the dura for a considerable distance at the base and sides. A very small part of the tumor, lying at the center, was distinctly visible and the microscopic appearance at the upper part of the ninth dorsal vertebra, which was perfect in its formation, was that of a tube within a tube, with nerve-tissue intervening, the external tube being formed by the membranes of the cord, the inner, the dural central canal. Upon examination of the vertebrae, the spinous processes and laminae of the eleventh and twelfth dorsal and those of all the lumbar and sacral were absent. Permission to examine the cord above or to make a more complete autopsy could not be obtained.

Dr. Elliott illustrated by means of diagram's his views concerning the successive steps in the lack of development which gave rise to the condition described.

V. The cause was not then searched for, that the mesoblast was concerned alone in the formation of the skeletal tissues, and he thought that it was proper, therefore, to confine its function to that part.

Dr. Elliott thought the case should be regarded as one of lack of development in nervous tissue as well, which is formed from the upper layer, or the epiblast.

Dr. Charles H. Brown presented two sets of cystic ovaries removed by laparotomy—hydro-salphinx.

The first was especially interesting on account of the mental condition of the patient. It was a case of acute melancholy, and regarded it as thirty-two years of age, gave birth at a child and six weeks afterward began to be retiring and manifested symptoms of mental depression, and finally simple melancholia became well developed. During this time she complained of a great deal of pain in the pelvic region. At childbirth she had a post-partum hemorrhage of considerable severity, and was a long time in recovering from her confinement. On examination he found the uterus enlarged, in a condition of subinvolution, there was laceration of the cervix, and in Douglas' cul-de-sac a body could be felt which was tender to the touch, and the patient suffered extreme pain when the body was subjected to pressure. Dr. B. F. Dawson examined the patient and regarded it as a case of dilated ovaries. It was decided to remove the organs by laparotomy, and the operation was performed with the result of finding both ovaries enlarged and cystic, and both Fallopian tubes in the condition of hydro-salphinx. The patient was doing well. The change in her mental condition was very marked, and at the end of twenty-four hours after the operation a very noticeable improvement was manifest, which had steadily and less severe. Whether or not it would be permanent could not yet be stated.

Cystic Degeneration of the Broad Ligaments—Hydro-Salphinx.

Dr. Brown also presented two other ovaries which were enlarged and, together with both broad ligaments, also in the condition of hydro-salphinx, were removed by laparotomy. The patient, about thirty-one years of age, was doing very well.

Dr. R. W. Amidon presented specimens with the following history:

Convulsions—Bromic Ulceration—Dilated Stomach—Congenital Hypertrophy of the Left Ventricle of the Heart—Congested Kidneys and Spleen.

Male, aged seven; bright and willful. There is insanity in the family, also phthisis. Mother hysterical. The child had measles when three years of age, after which the mother thinks the child had general oedema. The child began to be restless. It began at first of a nervous nature, and confined to the right hand. Soon these seemed to become accompanied by spasmodic manifestations, which in the last year have become general. As described by the mother the attacks consist now of a fall, first tonic then clonic convulsions, eyes half open. Has not been able to breathe or froth at the mouth. Attacks now principally at night, coming immediately on going to bed, when he has one after another till midnight. Of late has had two fits of same nature in afternoon. Appetite is insatiable, bowels regular. Has taken bromide of potash off and on for four years. Two years ago went one entire summer without medicine or attack. Attacks recommenced and bromide was again resorted to. Is now (May 2, 1864) taking .60 t.i.d. in pill form with some strychnia. For last few months has had a lesion on legs and about the eyes, which proved on examination to be a condition known as ulcus elevation—probably of bromic origin.

On examination the tongue is found coated, palate quiet; pulse, 140; speech not thick, but manner bromic. Said there were no cerebellar phenomena, and the fundus oculi was normal.

Dr. Amidon suggested a stoppage of the bromide (it never seemed to control the paroxysms in the least), with the view of noting its effect on the general condition of the patient, the fits, and the cutaneous lesion. The bromide was stopped about April 19th.

May 24th.—Dr. Amidon had an opportunity to witness the convulsions. While asleep the patient would stiffen out and stop breathing. The face would first get red, then dusky, the eyelids would twitch and resist any attempt to open them. A cry, resembling the epileptic, followed this stage, breathing recommenced with slight stertor. The eyes opened in conjugate, the right, the pupils dilating somewhat. When recovering the patient cries a little in a plaintive, frightened way, and keeps on sleeping. The only convulsive movement in these attacks was a straightening out of the legs. Sometimes there is slumbering on the pillow, and occasional wetting of the bed. The mother said there had been no day attacks lately, and fewer and less severe ones at night, and during the first sleep. These attacks were of a very nondescript character, some very epileptic in their manifesta-
Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from February 2, 1884, to February 9, 1884.

Barnett, Richards, Captain and Assistant Surgeon. Granted leave of absence for six months on account of disability. S. O. 13, par. 8, A. G. O., January 16, 1884.

Official List of Changes in the Medical Corps of the Navy, for the week ending February 9, 1884.

Van Ruypen, W. K., Surgeon. From the U. S. S. Powhatan to the Navy Department, as Assistant to the Bureau of Medicine and Surgery, and Acting Chief of that Bureau.

Overhling, A. A., Surgeon. From special duty at Washington to the Powhatan.

Medical Items.

NEW YORK COLLEGE OF VETERINARY SURGEONS.—Peter Peters, Veterinary Surgeon, writes: "Of page 131 of the last number of THE RECORD, I notice the following: 'The Columbia Veterinary Medical College and the American Veterinary Medical College have united, and New York has now but one veterinary school.' The above statement, which I have no doubt you made unintentionally, tends to mislead the public. The facts in regard to the above are about as follows: The New York College of Veterinary Surgeons was chartered by the Legislature of this State in 1857, and went into operation in 1862, at 205 Lexington Avenue. After several years of successful work, difficulties arose between the Trustees and the Faculty, resulting in the resignation or discharge of the latter, who organized the American Veterinary College in 1875. A new Faculty was selected, but at the end of one or two years new difficulties arose, and the Trustees discharged several of the professors, who organized the Columbia Veterinary College in 1878. A third Faculty was elected soon after, but for reasons best known to the Trustees, the active operations of the College were suspended until the fall of 1883, when the Board of Trustees and the Faculty were reorganized and a building, 332 East Twenty-seventh Street, was procured and a course of lectures commenced on October 1st. The New York College of Veterinary Surgeons is the sole legal veterinary body in the State having authority to grant the degree of Veterinary Surgeon. The schools above mentioned were incorporated under the law of 1848 for the incorporation of libraries, charitable societies, etc., and have no authority to grant the degree of Veterinary Surgeon."

PERITONEAL ABSCESS IN CHILDREN.—Dr. Goodhart has published notes of three cases of peritoneal abscess in children. The question of treatment in such cases requires great consideration; on the one hand, there is risk of pus gravitating into the hypochondria if a free opening be not made; on the other hand, there is a difficulty of draining the cavity of the peritoneum if an opening be made. Many cases do best if left to nature in young children, as an early incision may only open one abscess and leave several others.—London Medical Record, December 15, 1883.
Original Lectures.

ON THE

METHODS OF STUDYING THE BRAIN.

Abstract of the Cartwright Lectures, delivered before the Alumni Association of the College of Physicians and Surgeons, New York, Feb-

uary 2, 4, and 6, 1884.

BY BURT G. WILDER, M.D.,

Professor of Physiology, Comparative Anatomy, and Zoology in Cornell University, and of Physiology in the Medical School of Maine.

LECTURE II.

METHODS OF MANIPULATION: REMOVING, PRESERVING, AND EXAMINING THE BRAIN.

The average first-year medical student in attempting to remove the brain usually lacerates it with saw and chisel; tears it in the effort to keep the sacred skull-cap entire; injures it yet more in the process of extraction, and places it upon a flat surface, where its own weight completes the rupture of delicate connections, and hopelessly distorts its shape. Here he leaves it, perhaps for a day or two, probably drying, and possibly freezing or decomposing, according to the temperature. He then transfers it to a basin or pail, covers it with strong alcohol, notes with satisfaction that the surface rapidly hardens, feels sure of finding out all about the brain, and sees himself a future neurological expert, or even an asylum superintendent. In due time, armed with his “Gray” and a large knife, he succeeds in identifying the cerebellum, the optic chiasma, the orifice left by tearing off the “pituitary body,” and the pons Varolii. He also recognizes the medulla oblongata, and of Ranson’s “grey transverse vesi"" until artificially produced. He then slides the brain secundum arum, and so great is his pleasure in demonstrating the “centrum ovale majus” that he is not seriously disturbed at the presence of an unexpected root in the callosum and of an irregular orifice on each side. Continuing his operations, however, he finds the interior of the brain little more than a mass of nearly homogeneous pulp; at first fears that the alcohol was too weak, but, when satisfied upon this point, suspects that the names in the books have somewhat the same significance as those of the heavenly constellations, modestly admits that he may not be sufficiently advanced to study the brain, and resolves that, when he is personally prepared for this branch of inquiry, his armamentarium shall consist of not a scalpel, but a spoon.

Not only does the foregoing fairly describe what often happens, but there is little reason why it should not happen always. In what manuals of descriptive or even practical anatomy are there given adequate directions for the removal, preservation, and dissection of the brain? In what medical college do these matters form a topic of extended instruction? In what medical museum are they exemplified? How far is the average graduate prepared to make a necropsy for the sake of determining any critical encephalic question?

The fullest directions known to me are given in the "Practical Anatomy," by Heath, edited by Keen. The works of Quain and Allen give no directions at all, and, in the last edition of Gray, they are comprised within seven lines. The manuals of Delafeld and Bevan Lewis have rather a pathological than a normal bearing, and certainly presuppose too much knowledge and skill upon the part of the reader.

Medical students seem to be credited with an inherent notion as to the way of removing a brain, as if the head were merely a nut to be cracked and emptied. Has it never happened in a medical school, that the exposition of the structure of the noblest and most intricate organ of the body has occupied less time than was devoted to the description of a few ligaments and bones? Has it not sometimes consisted in taking a brain, which was removed in twenty minutes, dashing it upon the table with an air of familiarity such as the baker displays toward his lump of dough, and hewing it into incongruous slices or tearing it to display superficial conditions? Has it not resulted that the principal acquisition of the students therefrom has been a profound conviction of the self-confidence of the demonstrator?

Are there not, in large cities of the United States, museums connected with populous medical schools, yet containing, perhaps, a few animal brains, but none displaying the normal human organ; perhaps a series of encephalic tumors and abnormalities, but no normal structures; perhaps even plenty of skulls, but no brains at all? If the prevalent customs are what they should be, how is it that the following sweeping assertion of a distinguished medical anatomist has stood upon the pages of a leading American medical journal without an attempt at refutation?

"In our colleges . . . the only point of technic the medical student is taught is how to use his knife and forceps in dissection. He is given no instruction on the art of exploring viscera or gland-duets, the methods of taking out the brain or spinal cord, the preservation of anatomical specimens, or the thousand and one things that he needs in making an autopsy or in preserving specimens. Judging from the condition in which specimens are often presented for inspection at our medical societies, it is evident that not one physician in a hundred knows the use of alcohol as a preservative."—The American Journal of the Medical Sciences, January, 1883.

Why, finally, in the case of that brain upon whose configuration alone it was thought by some might depend the decision as to whether there had been committed two murders instead of one, why was it possible that this infamous yet precious brain should be removed hastily and by the ordinary barbarous method, weighed in a grocer’s scales, neither photographed nor even sketched, and, in short, as regards its gross anatomy, so inadequately examined as to neither advance science nor establish justice? Not the brain of the most insignificant cat should be so lightly dealt with as was the human brain whose condition, whether cause or merely concomitant, presented the most solemn psychological problem of modern times. Whatever may have been the reason for
The absence of proper facilities for examination and for the neglect of such opportunities as may have existed, since the determination of Guiteau’s insanity was in no degree aided thereby, for the credit of the medical profession of this country it would have been better that his brain should not have been removed at all.

Old ways are not necessarily obsolete, and sometimes it is discovered that time-honored customs have nothing to recommend them save their antiquity. Notwithstanding, therefore, its archaeological respectability, I am forced to characterize the well-nigh universally employed method of getting at the human brain for microscopic purposes, by “inserting a strong hook and giving a quick jerk,” as anatomically futile and artistically brutal, alike disrespectful to the organ concerned and to the operator as a member of a learned profession; upon the whole, it is less admirable than the splitting of a pig’s skull by the butcher for extraction of the brain as an article of food.

The principal features of the methods employed in the Anatomical Laboratory of Cornell University for the microscopic study of the normal brain are as follows:
1. The initial determination, if possible, of the use to be made of a given brain.
2. The concentration and preservative effort upon the parts especially desired, and, in some cases, a reduction of the mass to the region containing these parts.
3. The exclusive employment of processes presently exsiccating upon formalin for purposes of preservation.
4. The injection of alcohol steadily, for from one to ten days, into the arteries, so as to harden the brain in situ.
5. The demonstration of the forms of the ventricles, and the contour of their pia matters of the injection into them of alcohol, or of some mass capable of solidifying into a cast.
6. The systematic and intentional mutilation or even destruction of the skull for the sake of the brain.
7. The removal of the adult calva, after the usual circular incision, by hemisection a little laterad of the meson.
8. The exposure of the brains of fetuses and small animals by means of nippers, the trephine, and the dental engine.
9. The avoidance of all pulling upon the brain, either active or from its own weight, by the observance of care in all manipulation, and by the constant support of the organ in brine.

In general, a treatment of the brain in a manner commensurate with its complex structure, its high office, the value of the information to be gained from it, and, last but not least, our own self-respect and consideration for our patients; for he who is not familiar with rough with the dead is certainly in danger of occasional disregard of the living.

In the following amplification of the methods just named, the scope of the present course and the lack of time confine me to the more novel and important features.

Lateral hemisection of the calva.—The scalp is divided, as usual, by a transverse incision from ear to ear, and the flaps reflected as far as possible either way. A cord is carried around the head from about 1 cm. dorsal of the occipital protuberance, at a level with the ends of the scalp incision; if the string be kept in the same plane, it will cross the forehead and dorsi of the brows. This string is held steadily in place, and a light cut or black mark made along its entire length. With this as a guide, a firm, clean cut to the bone is carried about the skull, and the saw—which should be straight and sharp—is used along this cut. The operator should stop at frequent intervals and ascertain whether he has penetrated the dura mater by means of the point like that of the probe-end of the “tracer,” the bone should be completely divided, excepting at four points, say at or near the four “corners” of the head. The string is then carried over the head about 1 cm. dextra of the meson, a guiding cut made as before, and the calva hemisected along this line. If the dextral piece does not readily come away after division of the two corners, a small, narrow-bladed palette-knife is passed between the dura and the calva first in the temporal region, where the latter is usually thin. Neither now nor at any time force is to be used.

The dural adhesions along the superior longitudinal sinus are now within reach, and may be loosened by the palate-knife, with a slight weight, unless constantly supported. The body is therefore raised to the level of a large pan or earthen dish full of brine, about twenty-two per cent. Good dairy salt should be used; if the salt is not clean, the brine is turbid and obscures the dissection. If it is desirable to avoid the spilling of brine, the vessel containing it may stand in a pan or tray. With the palate-knife the dura is separated from the skull as far as possible on all sides. In this way, by a little care, and by using a narrow, sharp-pointed knife for severing the olfactory filaments ectad of the dura, the *lobi olfactorii* may be removed entire. The dura must be divided along the margin between the anterior and middle fossa, as well as between its edge and the ponticulus.* The optic nerves are to be cut as soon as seen, and the fundus divided immediately afterward; if the hypophysis is wanted, it can be separately extracted after removing the brain. The subsequent steps in the operation would take too much space if described in detail, but, if the brain is constantly supported in the brine, the need of no trouble. When removed, its dorum is still covered by the dura, and for some purposes—as, e.g., the study of the base while fresh and alcoholic injection either vascular or entocutaneous—it may be retained with advantage.

The exclusive use of alcohol.—For primary immersion or injection the alcohol is fifty to sixty-five per cent., and the strength is increased to ninety-five per cent, more or less rapidly, according to the size of the mass to be penetrated; with a small and thin-walled brain, like that of an embryo or *Necturus*, the full strength may be applied within six hours; with a large mass, as many days should elapse.

Affirming that alcohol is an efficient preservative of nervous tissue for macroscopic study, I neither deny the usefulness of other agents nor claim that alcohol is altogether adapted for histological purposes. The trials of other liquids in the anatomical laboratory of Cornell University have not been sufficiently extensive or systematic to warrant any generalization therefrom. Some of the other agents are cheaper than alcohol, but when the latter is obtained free of tax (as it may be for any museum or educational institution, under certain regulations) the cost is slight. How far alcohol will answer for histological purposes is not yet, I think, well determined.

The low temperature.—The value of this condition as an adjuvant to direct preservative agents is well known; indeed, an essential piece of laboratory furnishing is a refrigerator of some kind. For some purposes an ordinary ice-chest, opening at the top, serves a good purpose. But all operations requiring a low temperature are more conveniently carried on in a cold closet or small room adjoining the laboratory. Such a place may be temporarily provided by inclining a window and suturing it by means of a moderate sized partition; during cool weather a sufficiently low temperature may be secured by simply opening the window.

Mental hemisection of the brain, either before or after removal from the skull.—For the study of the fissures and gyri, and of all parts excepting such as lie directly upon the meson, the brain is well adapted if hemisected either before or after removal. Nor need the head be
frozen in the former case. If the saw be sharp and the teeth not much "set," the falc may be split in two and the hemispheres preserved. As this, however, requires considerable care, and the use of a sort of mitre-box or macrotome, it is desirable, to insure the safety of at least one meal surface, the hemi-section should be made 1 to 2 mm. laterad of the meson, and the adherent portions of the opposite side of the brain removed afterward with a scalpel. Each hemi-encephalon is very easily removed from the skull.

If the brain has been removed entirely, it may be hemi- sected with a large and very keen and thin knife, alcohol being poured on it as the section is made. The brain should be steadied by an assistant, and rest on a bed of cotton in a long, deep pan of brine.

The hemi-encephalon is to be hardened while resting on its meson upon a flat surface, preferably of glass. Since the bottoms of jars and dishes are rarely flat, the brain should rest upon a separate disk of glass which may be lifted from the vessel without touching the specimen. For two days the brain should be made to rise a little from the glass every few hours, in order to permit the anterior end to ascend to the mesial surface; then for a day it may be supported on its lateral aspect in a bed of cotton to prevent distortion.

Hardening the brain in situ by arterial injection of alcohol.—If not only the fissures are to be studied, but also the configuration of the whole brain is to be determined, the above-named method should be employed. Alcohol, injected into the cerebral vessels, may be cleared by the repeated injection of tepid water, until what escapes from the veins is uncolored by blood.

A canula is then secured in an artery leading to the brain; or, if it be desired to anject the heart in situ, together with other parts of the body, one canula in the posterior wall, and another in a pulmonary artery. These canulas are connected independently, or together, by means of a T-tube and rubber tubing, with a reservoir of alcohol, which is set upon a shelf at a sufficient height to insure a flow, or raised and lowered by means of a windlass. The animal or brain should rest in a vessel into which the alcohol escapes as it flows from the veins or oozes from various surfaces, natural and cut. The same alcohol may be used over and over, its strength being restored or increased by the addition of fresh alcohol.

As soon as there is reason to believe that the brain is so far hardened as not to be distorted by its own weight, a part of the calva may be removed; as above described, and the canula is inserted. This permits the escape of the alcohol in which the specimen lies, and any possible distortion may be corrected by the half of the brain which remains inclosed.

UNUSUAL PARTURITIONS—TWINS WITH SEPARATE AND UNBROKEN MEMBRANES.—Dr. E. R. Du Val, of Fort Smith, Ark., writes: "In your issue for December 29, 1883, I notice on page 718, 'Two Unusual Parturitions.' I have to report a similar case to that of Dr. L. Byron Dawley, of Seneca Falls, N. Y. January 12, 1868, I was called to Mrs. C.—, primipara, aged twenty years, in labor with twins, boy and girl. The membranes were advanced beyond the vulva fully two inches, were ruptured with difficulty, foot immediately appeared, followed soon by the fetus (boy) in its entirety, still-born. In half an hour after a second fetus (female) was delivered, child, membranes, and placenta at once and together; the child was completely encased in the membranes, which were so thick as to require considerable force with the nails and fingers to break them. The child (girl) did well and is now a young lady, sixteen years of age. The mother made a satisfactory recovery, and has given birth to several children since."

ARSENIC AND DIGITALIS IN PHLEITIS.†

BY A. JACOBI, M.D.,
CLINICAL PROFESSOR OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

Many a case of phlebitis, or rather many a case of pulmonary affection known to terminate in phlebitis under most circumstances, heals spontaneously or remains dormant. At least we have reason to conclude so when a number of cases with the same physical symptoms one or more never develop into phlebitis, while the others run their complete courses. As the proofs of incipient phlebitis we consider catarh of the apices, which is always attended with the presence of broncho-pneumonic deposits, of either recent or old date; so old, indeed, they may be that the history of their development dates back to infancy or childhood. Many cases of broncho-vesicular respiration over the upper, usually right lobe, diminished respiration, slightly bronchial expiration, moderate amount of dulness on percussion, and retraction of the supra-or sub-clavicular region are the results, quite often, of a single attack of well-remembered inflammatory disease. Add to this a flat chest, prominent shoulders, known hereditary disposition, persistent anemia, and constitutional debility, tendency to catarh, and occasional slight cough, and your diagnosis of incipient phlebitis leaves nothing to be desired. But this condition does not necessarily lead to pulmonary disintegration and general consumption, but may remain stationary, and even improve to such an extent that the symptoms are preserved. As soon as the disease becomes more normal, the subjective symptoms easier, and the weight increases.

If that be true, and known to be so by every practitioner, if spontaneous recovery may take place, why, the inference is that—this spontaneous tendency being given, recovery is the more possible and probable under the influence of well-directed medicinal and dietetic treatment.

Caseous deposits, both glandular and pulmonary, are often found in post-mortem examinations where death had occurred from some disease not connected at all with pulmonary disease, in an inert condition; they meant nothing else during all the period of their existence but so much less respiration area. Practically that which is phlebitis retarded or stopped in its progress. Even repeated attacks of broncho-pneumonia, with deposits leading, generally, to consumption, will finally cease, fever and cough will disappear, the general health will improve, and the lungs be in a sufficient condition for practical purposes.

It is only the last stage, when abscesses form, pus will be expectorated, the blood get deprived of albumen, blood-cells become diminished in number, oxygen not admitted in sufficient quantity because of the scarcity of blood-cells, assimilation be impaired and weight reduced by perspiration, diarhœa, and sleeplessness—and when finally pus will be absorbed—that the chances of recovery become less. Hecic, like every other pyemic fever, is apt to lead to death. But even such cases have been known to improve, or recover.

The treatment has to vary according to the stage; the period of gradual preparation, that of inflammatory action, that of pyemic fever, have their several indications. It has frequently varied in accordance with the theories held concerning the nature of the disease. There were those who took every form of phlebitis for a nutritive and diathetic disorder, those who saw in it a species of inflammatory disease in different shapes and degrees, those who looked upon every case and form of phlebitis as an infectious disease either of chemical, or as modern bacteriomania will have it, of parasitic nature. These different forms have their different indications for medical treatment.

† Read before the Medical Society of the State of New York, February 7, 1884.
On the effects of arsenic Isanard wrote a book in 1867. He administered arsenic mainly in malaria and phthisis. In both he explained its usefulness by its effect on the nervous system. He claimed that suppuration, debility, emaciation, vomiting, diarrhoea, and constipation would improve or disappear by it. The doses of arsenious acid used by him amounted to one centigramme (one-sixth of a grain) up to five centigrammes daily.

If there be any medicine which, besides quinine and mercury, has been called a specific in many diseases, it is arsenic. It is known to act as a poison, and a strong caustic. It prevents putrefaction, though as a real antiseptic it ranks even below salicylic acid. It acts very favorably in malaria, chronic skin diseases, maladies of the nervous system, and has considerable and sometimes unique effects in the treatment of lymphatic and lymphosarcoma. In small and frequent doses it improves connective-tissue growth, it thickens the connective tissue of the stomach, and increases peristalsis and oseal deposits. In the latter respect it is surpassed only by phosphorus, on the curative effects of which in subacute and chronic bone diseases I read a brief paper before the Academy of Sciences; it is also said to improve the sexual desire and power, and the physical courage of animals. Thus there is a variety of effects, the uniform cause of which remains to be found. It can be traced back only, it appears, to the action of the drug on the cell. It is true that the different organs mentioned have cells of different structure, appearance, and function, and to them, not to their different varieties do not differ at all. At all events oxygen acts on all of them in the same manner, albumen is absorbed by them all, and osmosis regulates their circulation equally.

The increase of cell growth in all the tissues mentioned points to the mode in which arsenic must develop its action. It cannot accomplish what it is known to do without local stimulation and irritation, which when moderate improves growth, when exaggerated (by large doses or in predisposed persons) leads to granular degeneration.

Arsenious acid, when in contact with the constituents of the living organic cell, is oxidized up to arsenate acid. This is often reduced again to arsenious acid. Based upon these observations, Binz and Schulz have advanced the theory that the cells are kept in a constant condition of irritation by these changes, which involve an equal variability in the conditions of the atoms of oxygen. Tissues endowed with a rapid metamorphosis must necessarily be affected more than others, and those in which the metabolism is still more pronounced must become more affected by degenerative processes, while a moderate effect results in irritation only. To accomplish this, it is immaterial whether arsenious acid acts as such or in some chemical combination. Its action, as long as it is restrained within certain limits, has been utilized by Hans Buchner for practical and theoretical purposes. The former consists in its administration for as little as possible in the attempt to fortify the bacillus theory. In his belief phthisis can be prevented by keeping out the bacillus. This is done by stimulating and gently overnourishing the cells, and thereby increasing the power of the organism to resist the invasion of the bacillus enemy. His theory is more shaky than his results. He relies on arsenic as his main medicinal resort in phthisis, and finds fault in Isanard only because of his using arsenic for curative only, and not for preventive purposes. In this remark lies the explanation of the effect which I claim myself also.

Consumption is almost always of long duration. The same nutritive disorder, the same inflammatory attacks recur frequently during the different stages. Besides the origin of the disease, therefore, many attacks, each of which can and must be treated when perceptible, or prevented before they fully develop. If such prevention be thorough, phthisis will remain dormant. That effect is accomplished by rational dietetics, climatotherapy, and finally by arsenic. I know it has been used formerly in that diseased condition called consumption, but the reporting of new experience does no harm. Besides, where two do the same thing, it is not the same thing after all, and the method of administration is more important than the fact of administering it. Under the permanent use of arsenic the infiltrations diminish, elastic fibres disappear from the expectorations, the strength improves, and the weight increases. Of this result I have convinced myself in a great many cases while they were in the incipient stages.

Trouseau and others recommended arsenic, in chronic pneumonia, as well as in angina, the trophic ulcer, and asthma, in the shape of cigars. The indications in many cases are correct, the method of administration is very much less so; for there is no remedy the doses of which are less subject to, and tolerated in such uncertainty, as the smoking of arsenic cigars would imply.

Small doses of arsenious acid do not interfere with the efficiency of saliva, and gastric and pancreatic juice, nor is the stomach itself affected by it. In some cases there is a slight sensation of pain or hunger, the result of which is increased appetite, and ingestion of food. However, as this larger amount of food is not followed by indigestion, the powers of the stomach must be presumed to be increased. Undoubtedly the innervation of the organism and processes of general nutrition is improved also. This effect is so well known to farmers and veterinary physicians that animals are supplied with arsenic for the purpose of strengthening and fattening. Its use among miners is well known. In many cases of anemia it is the best alterant and nutritious food.

Hans Buchner asserts that the incipient stage is not the only period in which arsenic proves effective. That is true. It has the same, or rather a similar beneficial effect in the later stages. But he claims that complete recovery has been accomplished in the most severe cases, that perspiration and fever will cease, the pulse become less frequent and stronger, and the vital capacity increase even in far-advanced cases. This I believe to be overdrawn. Particularly in regard to the hectic fever I have almost always been disappointed. I believe that even digestion was not at all improved by arsenic in that stage. Thus it has become my rule not to prescribe arsenic at all while the fever is high, but to begin or return to it as soon as the temperature has a tendency to descend. I neglected to use the arsenic I had very often the satisfaction of improving the condition of very doubtful and far-advanced cases.

The doses ought not to be large. Nausea, colic, diarrhoea, oedema of the eyelids are contraindications to the continuation of its use. One-fifteenth, or one-tenth to one-sixth of a grain of arsenious acid, daily, is a sufficient dose for a child, if it is of average size at time.

In order to render it less liable to give rise to disagreeable symptoms a little opium may be administered with it. In most cases of incipient phthisis this combination is pleasant and useful. In such as show intestinal symptoms at an early period, its joint administration is a particularly happy one. Still it may be remembered that gastric symptoms, attending the use of arsenic first, will be apt to disappear soon.

The preparations I use are either arsenious acid or Fowler's or Pearson's solution. The former it is best to give as a pill, in such combinations as I shall allude to shortly. Fowler's solution, three drops, or Pearson's solution, six drops, three times a day, in a few ounces of water, administered after meals, and gradually increased.

2 Arch. f. exper. Pathol. u. Pharmacob. xl, xili, xiv, xv.
3 Die aetiologische Therapie und Prophylaxis der Lungentuberculose. 1883.
5 In the discussion following the reading of these remarks Dr. Drake gave expression to his favorable experience in regard to the use of arsenic in the fever of phthisical patients.
will act favorably. In but few cases the former had to be exchanged for the latter, because of the intolerance of the stomach.

In connection with the above remarks I venture to submit a few words in regard to another remedy which I believe to have been beneficial in a great many of my cases. Again I have no new remedy to advise, but desire to state that an old one has, in the course of time, decades aided me much in relieving my patients. If I speak of as trite a drug as digitalis, I may be permitted to add, that while nothing that I say may appear new, it has seemed to me as if from year to year I learned better how to use it.

In the vertebræ, digitalis increases the energy of the heart, and the heart becomes more efficient; but it increases arterial pressure and diminishes the frequency of the pulse. In this connection it is of no consequence whether the irritation of the inhibitory nerve is the primary or the secondary element. By increasing the pressure in the arteries, besides favoring the secretion of the kidneys, it improves the pulmonary circulation, empties the veins, and thereby accelerates the circulation of lymph and the tissue fluids. Thus while having an immediate effect upon heart and lungs, it exerts a powerful influence on the metamorphosis of organic material, assimilation and elimination, that is, nutrition in general.

Thus both the local and general effect of digitalis are involved in all stages of phthisis. While, however, they may relieve in the last, they are a healing element in the first stages. The congestive and nutritive changes constituting the preparatory, and, in part, the advanced stages of consumption, are favorably influenced. I seldom treat a case of phthisis without it. Very little care is required to avoid disagreeable results. Cumulative effects are either the consequences of excessive or too frequent—unnecessarily frequent—doses, or of the selection of improper preparations. Such as are soluble in water with difficulty only, ought not to be used, for it may happen that, having been inert for some time, a large amount may enter the circulation at once. Particularly is this true of digitalis, which is by no means a soluble alkaloid, but a crystallizable glycoside. I use the infusion, the tincture, the fluid extract, the extract. Their relative values I do not desire to discuss, except in regard to their advisability in phthisis, and the possibility of continuing them for a long time. Patients of that class we see from time to time only; they require advice and prescription for a protracted period; as a rule, their digestion is not impaired, and therefore in many an alleged dyspeptic patient is affected with gastric disturbances first, and has his attention drawn to the lungs by his physician, who discovers the cause of his gastric catarrh in the retarded circulation of heart and lungs. In this case the stomach exhibits the peripheral symptoms of the distant diseased organs in the same manner in which a local disease of the brain or cord shows itself first, in affections of peripheral nerves. Now, whenever the stomach is much affected, neither the tincture nor the infusion is tolerated long. The latter may be given in three daily doses of half a tablespoonful each, or in two, of three teaspoonfuls each, for some time. But I seldom risk to recommend it for more than five or six days in succession without seeing the patient. The fluid extract has often disappointed me, I cannot tell why, nor do I claim to know why. What I mean to report is merely my experience. My main reliance is on the extract; my almost universal method of giving it is in the form of a pill, in such combinations as will suit the individual case. The stomach does not object to this preparation at term, without being overloaded. Be it ever so trifling in degree, it should be immediately closed by sutures. First, to increase the patient's immediate comfort. The application of the sutures is but momentarily

CERTAIN MATTERS OF TREATMENT WHICH SHOULD BELONG TO THE LYING-IN ROOM.

BY HENRY F. WALKER, M.D., NEW YORK.

The physician's office in the lying-in room is, in one respect, peculiar. It is the only time in his professional life that he is called upon to superintend, and perhaps aid, a purely physiological process.

In all his other duties he deals with disease, but in the care he gives the parturient woman he is at hand to avert disease. The nurse being the chief observer in the case, his endeavor should be to leave his patient in as good condition as she was before the parturient act. But too often he is called to see a well woman, and when he discontinues his attendance he leaves a chronic invalid.

I purpose to speak of some matters of care, of both mother and child, which I think properly belong to the lying-in room. Attention to these would, I think, diminish invalidism in women whose health motherhood has imperilled, and in the infant avert dangers which threaten its welfare.

My paper, which does not claim to be exhaustive, will be on "Certain Matters of Treatment which should Belong to the Lying-In Room." I propose to speak only of such troubles as may attend upon natural labor, but which may, nevertheless, leave a woman with health impaired, and years of feebleness before her.

The first in the natural order, as being first in the order of time, is the immediate care of the perineum. It can be fairly stated that no woman is delivered of a normal child, at term, without some interference. Be it ever so trifling in degree, it should be immediately closed by sutures. First, to increase the patient's immediate comfort. The application of the sutures is but momentarily

1 Read before the Practitioners' Society of New York.
painful, and though their presence may be recognized, the movements of the patient's body give no more suffering, with the sutures in position, than when the torn surfaces lap one upon the other. At the end of a week the soreness is gone, if union has taken place, while several weeks are required for the granulating surface to lose its tenderness and be shielded by mucous membrane.

Second, because the closed wound leaves one less avenue for septic entrance. If the wound heals by first intention the union is cemented in twenty-four hours, while the discharges seldom become poisonous before the second or third day.

These remarks apply specially to the slightest degrees of laceration, where the decision is between immediate attention and entire neglect. Where a greater injury has been inflicted it is better to close the perineum at once, because, besides the reasons already given in the lesser case, viz., the increase of the patient's comfort, and the lessened danger of septic absorption, a later operation will be required, and that is a matter of greater severity.

In these days, when operations are common, and every woman, or at least her bosom friend, has had special treatment, nothing is more common than for a woman to ask, at once, after delivery, if she be torn, and to express desire for immediate treatment. It is useless to attempt denial, but in this case of deliberate, and unnecessary, because, even popularly, no blame attaches to the accident. But, for that very condonation, blame does attach to neglect of such an injury after its occurrence. Results, too, are almost always favorable.

In my own practice an average of eight cases in ten have healed by first intention. A few times, from suspicion that a pronounced injury might be due to imprisoned pus, I have removed the stitches prematurely, but in no case has there been any untoward result. In some cases I have failed to operate and have regretted my neglect, but in no case where I have operated have I wished that I had pursued the other course.

It seems strange that this other habit than that of immediate closure of the wound should have obtained. In no other situation has it been the habit to prefer a healing by granulation to union by first intention. If a nostril were torn, the mouth gashed to double its size, the first effort has always been to bring the parts in close apposition and retain by sutures. But many a woman, newly married, has been able to suffer the slow torture of a possible healing by granulation.

As to the means to be employed, if not in one's pocket-case, they are always at hand. A button-needle and embroidery silk, or dentist's floss, have in several instances stood me in stead. The silk suture is preferable to silver wire. Its perfect softness and pliability prevent all the suffering which every contact with the twisted wires occasions. The union is as perfect with silk, and though there is likely to be a little suppuration in the track of the threads, the additional comfort that is gained in motion and dressing by using a pliable instead of a stiff suture is sufficient reason for employing the former.

The second matter—often neglected, but deserving of attention—is the most important of all, and consists in the condition of the uterus as to its position. Every woman should be examined by digital touch three or four weeks after delivery, or when beginning to move about freely upon her feet. Any descent of the uterus, or a slight alteration of normal axis is easily appreciated, but, what is of more importance, is then easily rectified. A light uterine support worn at this time, for a brief space, will achieve what no pessary could at a later one. I make such an examination, and if I find prolapsus or retroversion in the first or second degrees, I do not trust to nature, but attempt her aid by causing a pessary to be worn till involution has lightened the uterus, and the uterine supports have gained their tonicity and their normal size. I have sometimes found as one cause, that cases of threatened severity have thus been cured.

Several cases I have had that have been relieved of chronic retroversion by the use of a pessary during the period of involution.

In cases where the uterus lies lower than normal, but is antverted, less can and less needs to be done. The axis is nearly correct and attendant inconveniences are less, while nature, in this case, is more competent to remedy the fault. But here, also, slight support, by preventing passive congestion of the displaced organ, will in a measure diminish the tendency to a hyperplasia, which might result.

The nurse will usually tell the patient that the "sense of thing" is perfectly natural, and that it will disappear as strength comes. But in many cases the symptom is an indication of a true uterine displacement, which a little care will remedy, but which neglect will aggravate. There is no time so favorable to treat the malpositions of the uterus as that following delivery. The womb as well as its supports are then undergoing active change, and with proper assistance can regain normal strength and tone. We look to the parturient act to remove the mechanical dysmenorrhoea of the nullipara, and we may look to it also as a means of improving many cases of displacement, and most cases of hyperplasia, unless a lack of careful management, during the precious weeks following delivery, allow the troubles to aggravate. A few things of this kind neglected but deserving of care during the lying-in month, is the prepuce of the male child. Great attention has been called of late years to the influence of phymosis upon the child's nervous system, and I have had many instances where improvement in general health, as well as in local nervous disturbances, has followed the removal of an adherent prepuce. So manifest has this been to the parents, that when a male child was subsequently born in a household where a child had been circumcised, the mother has always been eager that the same operation should be performed on the successor. The popular voice is in favor of the operation.

It should be added that in the lying-in room. It is a well-known saying among nurses, that boys are worse than girls, more restless and fretful. This I think is mainly due to preputial irritation. My attention was first specially called to this condition by two cases which were unable, or very insufficiently able, to empty the bladder. The release of the prepuce immediately relieved the symptoms, stretching or a cutting operation being done. We only once in twenty-eight hours, urine almost regularly every three or four hours. The other, with even severer symptoms, was at once benefited, and all disposition to retention was overcome.

Since these cases occurred, I have examined the prepuce in every male infant, and have operated on all that seemed to demand interference. In the majority of cases at birth there is admission between the two mucous membranes, the orifice of the urethra and that of the foreskin not differing much in size. In cases where the preputial orifice allows, I push it back, separating the two agglutinated surfaces with a probe. This can be done, I think, in one-fourth the cases. In three-fourths without further force, the condition of the foreskin is needful. Of these I much prefer the latter method of treatment. A linear incision slitting the prepuce on the median line is all that is needful, and there is no necessity of circumcision. The splitting up the prepuce is efficient, and equal in appearance. Besides, a demonstrable foreskin is left, which some prefer. In manhood this method results in deformity; in childhood the result is doubtless in this regard; in earliest infancy the result is perfect, provided after operation care is taken that the foreskin shall heal, leaving the glans constantly exposed. The chief reason why the less operation is equally efficient, and therefore should be performed in early infancy, is that the cuticular and mucous surfaces are then equal and delicate. As the use of the penis, perhaps by its adhesion, seems to develop less rapidly, all growth is apparently limited to the outer surface,
which elongates in folding upon itself so that it quite conceals the urethral orifice. The form known as "little boy's prepuce" begins development early, but if the operation is made in the first fortnight the incisions in skin and mucous membrane are almost equal in length. In two months' time the prepuce with its infolded skin will be nearly double the size of the mucous lining covering the glans.

As to the time of interference, unless there be retention of urine, as in the two cases I mentioned, I believe that the rule established by Jewish and Mohammedan usage is a good one. By that time all possible septic trouble from the cord is removed, and the mother is too far advanced in convalescence to be troubled by any possible infection.

If the prepuce is slit back as far as the corona and the two mucous surfaces separated, there will be no after trouble, and at three years, save that the glans is uncovered, there will be little sign of the surgical interference. My reasons for advocating this plan are these:

Sooner or later the boy or man will require some treatment similar to this, the splitting of the prepuce or its circumcision. If likely to be required, all things being equal, it had better be done early than late. It is better that the child's system should escape the long nervous strain that the constant preputial irritation gives. If done early the lesser operation gives equally good results, both as to efficiency and appearance.

The points I have endeavored to impress are these:

**First.**—Examine every woman immediately after delivery, and if there is any laceration, even a trifling one, close at once with silk sutures.

**Second.**—Examine every woman when she begins to move about, and if there be displacement of any kind, anteversion, retroversion, or prolapsus, introduce a proper pessary with the hope that its temporary use during the period of intermission will establish a cure.

**Third.**—Examine at birth every male infant, and if the prepuce be so contracted or adherent that, with probe and pressure, the glans penis cannot be uncovered, operate by splitting the prepuce as far back as the corona with scissors or bistoury; the chosen time for operation, unless urgent symptoms present themselves, being the ninth day.

---

**ON THE SO-CALLED RHEUMATIC FOOT.**

By CHARLES F. STILLMAN, M.D.

NEW YORK.

The object of this paper is to draw attention to the means of relief which can be afforded a large class of individuals who suffer from a form of lameness attributed to a relaxation of the arch of the foot. This occurs most often in people of heavy frame, lymphatic temperament, and indolent disposition, and they are thereby incapacitated from taking sufficient active exercise for the requirements of the system.

Its existence in connection with the rheumatic and gouty diathesis has caused it frequently to be considered as one of their local manifestations; but it occurs so often independently of such systemic condition as to warrant its being considered rather as a complication when found in connection with them.

These patients are usually prevented from standing or walking by the severe pain which such exercise occasions, and thereby are caused to remain indoors, and often confined to the room or bed, the horizontal position alone giving relief. When walking is attempted the gait is most awkward, there being an effort to prevent the inner border of the foot from bearing the superincumbent weight, and this causes a peculiar characteristic waddle. There is erosion of the foot as a whole, and the inner surface touches the ground instead of the outer. Pressure over the junction of the astragalus and inner malleolus, and the borders of the mediotalar bones which present internally, causes pain, which is much aggravating if the patient stands. There is usually very little power of inverting or elevating the inner portion of the foot, and the tibial muscles are deficient in development.

Among the causes of this deformity the foremost is prolonged standing or walking, thereby fatigue the tibial muscles, whose function is to support the arch. When the arch of the foot is properly supported by vigorous muscles, its component parts are held together closely as to sustain the weight of the body without giving way; but if the muscle becomes fatigued either by too much standing or walking, and thereby relaxed, and if the person be heavy or of lax fibre, the arch flattens, and if the cause be repeated often it flattens to such an extent as to produce painful pressure upon articular surface, which is not normally subjected to those inflammatory conditions of the parts. An inspection of these cases reveals, 1st, complete flattening of the arch; 2d, apparent subluxation of the mediotalar bones; 3d, evasion of the foot as a whole; 4th, considerable puffiness behind and under the internal malleolus, and a wasted condition of the tibial muscles, the spine of the tibia being more prominent than normal, and occasionally the anterior half of the foot will be bent outward on the posterior at the mediotalar junction. By palpation the mediotalar bones are found to be abnormally prominent, although the deformity is comparatively slight. There is also a morbid relaxation of the tibial muscles and the ligamentous structures of the mediotalar and intertarsal articulations.

In the treatment of this condition there are three indications to be met. **First.** To place the bones of the foot in their normal relations to each other. **Second,** to re-establish the arch, and place the foot in such relation to the leg that the weight of the body when transmitted to the foot will be received by it while in a normal position; and **Third,** to improve the circulation.

To meet the first indication it is merely necessary with the hands to untwist the deformity, forcing the foot around into the position of a slight varus, and while in this position apply a broad strip of soft moleskin adhesive plaster, the edges of which should be nicked to prevent cutting the flesh. This strip of plaster should begin just anterior to the internal malleolus, and be drawn tightly around over the instep and under the arch to a point beyond the median line, so as to completely encircle the foot. This will retain the mediotalar bones in their correct position if the other indications are also met. The second indication, restoring or preserving the arch when the weight of the foot is borne upon it, is best done by having the edge of the insole of the shoe be in a normal arch and inserted in the shoe, being covered by thin muslin or leather to form a smooth surface for the bottom of the foot. This presents a firm and somewhat elastic support to the arch, and prevents its flattening. The heel and sole of the shoe should also be sliced or constructed higher upon the inner than the outer side, or an insole of this shape may be inserted inside the shoe. If the case be markedly severe, and the weight of the patient be so great, and ligamentous relaxation be so complete as to require still further support at the ankle, an inside spring may be attached vertically to the sole in such a manner as to be at an inclination, so that when the girth is buckled around the ankle the inner side and edge of the foot will be turned upward, forcing the patient to walk up on the outer side. This brace is rarely necessary, however, and when considered advisable can be so constructed as not to be apparent to the observer, being attached below to the sole inside the shoe, and passing vertically inside the shoe to the girth which is fastened to the leg just above the ankle. The third indication is met by faradization of the muscles, while the foot is held in the position of a varus by the hand of a surgeon, it being also desirable to have the patient voluntarily contract the muscles which return the foot in that position. This is a point of much importance in the faradic treatment, as it causes the faradic force to act supplementary
to the voluntary nerve-stimulus of the will. By a combined use of these agents these patients can be made so comfortable that they can attend to their ordinary pursuits and can walk long distances with comparative ease.

Florence House.

The treatment of writers' cramp and allied muscular affections by massage and gymnastics.

By J. Wolff, New York.

Writers' cramp, the inability of the hand to write, and, in a more extended sense, to perform the finer mechanical movements required in knitting, piano and violin playing, sewing, painting, telegraphing, etc., has been looked upon by physicians partly as a peripheral, partly as a central affection, and has hitherto been regarded as an unsolved problem. It sets in almost imperceptibly, manifesting itself first by a slight stiffness and occasional lancinating pain in the hand; by degrees the pain becomes noticeable in the wrist, in the arm, in the region of the shoulder, not rarely it extends toward the back. At this time the patient becomes conscious of an increasing sense of weakness in the hand; this is felt especially by the fingers used in writing, they begin to contract, the handwriting deteriorates, its legibility diminishes, and finally the patient either can no longer write at all, or at most can barely scribble on the paper with the greatest difficulty and fatigue. Corresponding to the involuntary opposition movements, there appear on the paper unintentional hooks, at times quite amusing blotches of ink, and all sorts of strokes disfiguring the handwriting. At last the fingers not only refuse to write, but are unable to perform all the finer motions, such as winding a watch, carrying a spoon to the mouth, knitting, sewing, etc., while any other work can be done without difficulty. But as soon as the pen, or the needle, is again grasped in the fingers the contractions recur.

For the cure of this affection all imaginable remedies have been tried: electricity, narcotic inunctions, sea, mud, and other baths, pneumatic and hydrotherapeutic treatment, tin, strychnine, myotoxin. They were all in vain; tenotomy has been performed, the entire range of therapeutics have been exhausted to no purpose; finally attention has been directed to constructing peculiar pen-holders, etc., in short, nothing has been left untried, but no results have been obtained. Possibly one or other auxiliary may have produced temporary amelioration. I call to mind the bracelet invented by Nussbaum in 1882; a pen-holder so constructed as to be guided by the extensors of the first four fingers and the abductors of the thumb—complete cure, however, has never been obtained.

It was recommended to write with the left hand, but difficulties arose from the beginning, and gradually the disease reappeared also in that hand. Hence nothing remained to the patient but to discontinue writing, pianoplaying, knitting, and all the lesser manipulations followed by spasm and pain.

No rest did help, and the patient had to submit to his fate. The physician had no remedy for him, nor did rest give him any that would enable him to support himself and his family.

The patient now applied to the writing-master, and in this, my former calling, I became familiar with this troublesome affection; but it was clear to me at once that mere instruction in writing, no matter how carefully adapted to the individuality of the trouble, would not suffice here. I was convinced from the outset that this disease, in general, could not be of a central nature, but rather must be a disturbance of the musculature involved, be its cause what it may, and for this reason, because it appeared only during the use of the muscles, but not otherwise.

Having familiarized myself with the mechanism of the hand and arm in their various motions in this activity, I comprehended where the first causes of the trouble should be sought, and I endeavored to enlarge and amplify this knowledge by a careful study of anatomy and the attendance of the lectures of numerous eminent physicians. Proceeding from this fundamental knowledge, I reviewed the activity of the entire nervous and muscular systems in their intimate connection, together with the most frequent disturbances related to organic life as a whole, I developed my method of treatment, which is not empirical, but is based on the recognition of the proximate as well as the general causes of the disease, and which aims not at a temporary, but a thorough and permanent cure of the malady.

The means employed in my method, in general, are massage and gymnastics combined in a novel way, their effects being mutually antagonized, and, moreover, the application of these two curative factors is carefully adapted to each individual case with special reference to the antecedent history and the general condition of the patient.

Let us assume, for instance, a pronounced spasm of the flexors. Here the muscular antagonism is pathologically altered, there is a spastic contraction of the flexors and abductors. In proportion as this continues the sense of weakness increases and the handwriting becomes more uncertain. The spasm increases, the weakness disappears and the cramp is cured.

However, the cramp does not affect all the five fingers, but usually only those actually engaged in writing—the thumb, index and middle fingers—of these either all the three, or only two, but never one alone, because the pen cannot be grasped and held with one finger only. Proceeding from this fundamental study to a review of the spasm I perform massage of these three fingers, beginning with the thumb, partly centrifugally, partly centripetally, as far as the wrist; I then cause the patient to execute different free motions, such as bending and stretching, spreading and contracting, continued for hours until the hand is fatigued, and these are repeated till the patient is able to move each finger voluntarily in all directions.

These manipulations, carefully repeated three times daily, have done me excellent service, and the affection, in most cases, was cured completely in from three to four weeks. But inasmuch as the spasm appears in different forms, and as its causes vary, the treatment of every single case must be adapted. Possibly one or other auxiliary may have produced temporary amelioration. I call to mind the bracelet invented by Nussbaum in 1882; a pen-holder so constructed as to be guided by the extensors of the first four fingers and the abductors of the thumb—complete cure, however, has never been obtained.

It was recommended to write with the left hand, but difficulties arose from the beginning, and gradually the disease reappeared also in that hand. Hence nothing remained to the patient but to discontinue writing, pianoplaying, knitting, and all the lesser manipulations followed by spasm and pain.

No rest did help, and the patient had to submit to his fate. The physician had no remedy for him, nor did rest give him any that would enable him to support himself and his family.

The patient now applied to the writing-master, and in this, my former calling, I became familiar with this troublesome affection; but it was clear to me at once that mere instruction in writing, no matter how carefully adapted to the individuality of the trouble, would not suffice here. I was convinced from the outset that this disease, in general, could not be of a central nature, but rather must be a disturbance of the musculature involved, be its cause what it may, and for this reason, because it appeared only during the use of the muscles, but not otherwise.
A CASE OF SUPERFETATION.

By J. W. LEWIS, M.D.,
Lancaster, O.

On December 21st I was called to see Mrs. K——, in her tenth confinement. She was a rather shabby German woman, aged forty-five. The labor was rather slow, but not particularly exhausting, and in due course of time she gave birth to a healthy, well-developed female child, at full term of gestation. Nothing unusual attended the birth, so that up to this point everything was satisfactory. But upon removing the child from the bed, and placing my hand upon the abdomen of the mother, I found the uterus contracted tightly over an apparently solid mass, measuring about eight inches in its transverse diameter, and about twelve inches in its longitudinal diameter, marking an ill-defined oblong square. Waiting as long as I thought it safe (on account of hemorrhage) for the uterus to empty itself, I proceeded to remove a firm adherent placenta, which presented the following peculiarities:

1. The placenta was twice the ordinary size.
2. On the free surface of it were a large number of well-defined nodules, from the size of a pea to that of a large hickory nut.
3. At least two-thirds of the placenta consisted of a peculiar lardaceous formation resembling cheese, and readily breaking down when pressed between the thumb and finger, showing a moderately well-defined fracture.
4. Near the centre of this placental formation, embedded in this adherent mass, it was my fortune to discover something over a pint of fluid, floating in which was a well-developed male fetus three and one-half inches in length, attached by an umbilical cord of small size to an expansion (of the cord) resembling a placenta on the inner surface of the cyst, evidently having received nourishment from the mother, as the fetus showed good nourishment and but recent death. The mother made a good recovery.

Progress of Medical Science.

LARYNGEAL CHOREA.—At a recent meeting of the Academy of Medicine of Paris, M. Blachez reported two cases of laryngeal chorea (Journal de Medicine de Paris, October 20, 1883). A child, the son of a rheumatic father, was taken with a frequent hoarse cough, without fever or pharyngeal congestion. Five days later the cough became paroxysmal and a little painful. There were no rales in the chest. The general condition was poor, and an appetite was preserved. General asthenia was present in the extremities. Belladonna, valerian, cold compresses, and sulphur baths having been tried without effect, recourse was had to bromide of potassium. The character of the cough became then modified. Instead of being hoarse and jerky, it resembled a slow chant of two identical low-toned notes. The duration of each attack was about three-quarters of an hour, during which the child seemed to be excited and his face was flushed. The history of the second case was but a repetition of the first. Dr. Blachez regarded the affection as a sort of incomplete chorea, the manifestations of which were confined entirely to the larynx, whose origin was explained by the rheumatic antecedents. The bromides had no more favorable influence than the other antispasmodics. The only remedy which succeeded in curing the affection was chloral. Its administration was followed by a febrile movement, and the author thought that this fever perhaps exerted a beneficial influence in causing a disappearance of the disease, as it has been observed to do in certain cases of pronounced chorea.

A CASE OF MELANCHOLIA IN A CHILD.—Dr. Kaval-efski relates the case of a boy, of eleven years, whose physical growth had always been slow, and who was weak and thin, but whose mental development had been nor-
mal, and who was good-hearted and of light disposition. At this time he had scarlet fever, followed by diphtheria and pneumonia, after recovering from which he was very weak and irritable and suffered from occasional night terrors. A few months later he had an attack of measles, and after this lost interest in everything, sought to be alone, cried for whole days without any reason, and imagined that he was always being pursued. He began to delude himself for months that he would die, and was continually begging people that they would not let him die. He would give only short answers to questions, and sometimes none at all. It was impossible to engage him in any continued conversation, and frequently he would repeat others' or his own words automatically. He was very anemic, had no appetite, and suffered from profuse perspiration. He was weak, yellowish, obd Play- liver, warm baths, and a life in the open air. Under this treatment he gained flesh, and his anemia was cured, and along with the physical improvement his mental condition gradually returned to the normal. The author remarks that this case is confirmatory of the opinion of Meynert, that melancholia is due to cerebral anemia.

— *Allgemeine Medicinische Central-Zeitung*, November 10, 1883.

THE RECIPROCAL ANTAGONISM OF POISON.—In a number of experiments undertaken to determine the antagonism between atropine and pilocarpine, Dr. M. Rossbach found that he could overcome the effects of the latter by means of the former, but that he was unable to antagonize the action of atropine upon the sweat glands and the pupils by the exhibition of pilocarpine, provided a sufficient quantity of the former were given. It made no difference whether the two drugs were administered together or one after the other. In studying these effects he recognizes two parts of the glands—the nervous and the cellular. Small doses of atropine and pilocarpine act upon the nervous parts, the former having a paralyzing and the latter a stimulating action. An apparent reciprocal antagonism may be noted when very small doses of atropine, acting thus as a paralyzer of the nervous portion, are overpowered by large doses of pilocarpine acting as a stimulant to both the nervous and cellular portions of the glands. But this antagonism is not seen when doses of the paralyzing drug large enough to act upon both portions are exhibited. The author makes the conclusion expressed above, that there is no true reciprocal antagonism between the two poisons. The toxic paralysis of any limited portion of the organ cannot be overcome by a drug acting as a stimulant to that portion. But the increased activity of any such limited portion, induced by any stimulating drug, may not only be antagonized by a paralyzing poison, but in spite of previous stimulation the part may become paralyzed.—*Allgemeine Medicinische Central-Zeitung*, No. 79, 1883.

THE BACILLI OF LEPROSY.—Several years ago Dr. G. H. Hansen, of Norway, discovered a micro-organism in leprous nodes, but as nothing of the kind had been noticed in any other chronic disease at that time he was rather skeptical as to the causal relation of the parasite to the disease. While he was engaged in these investigations he was visited by Neisser, of Breslau, who took some of the material home with him and succeeded in staining the bacillus, thus demonstrating its existence. About the same time, Hansen also was successful in his attempt to color the parasite. He had before this endeavored to inoculate animals but obtained no results. Neisser made a journey to Grenada to study leprosy, and while there made several attempts to inoculate dogs with the disease. In one instance, after a violent effort, a leprous nodule under the skin, a tumor was developed which he thought was a proof of the success of his experiment. There was no general infection, however, and it seems very doubtful whether the tumor was really of a leprous nature. Hansen inoculated two apes, one with a leprous nodule inserted under the skin, the other by injecting a drop of a culture fluid into the lobe of the ear. Both apes died, and though they were tuberculosis there was no trace of leprosy to be found in them. There was no tuberculosis of the lymphatic glands in the neighborhood of the parts in which the inoculation was practised, nor was there any ground for believing that the tubercular infection was the result of the introduction of the leprosy bacilli. The bacilli of tubercle resemble those of leprosy, so closely that it is difficult to distinguish them, yet they differ sufficiently to enable them to be recognized as separate organisms. It is possible that the bacilli of leprosy may only fructify in the human species, and in any case the negative results obtained in inoculations upon animals by no means disprove the contagiousness of the disease. Hansen is now trying to cultivate the bacilli in the solidified blood serum of different animals after Koch's method. He has succeeded in the case of human blood serum kept at a temperature of 96° to 102°. If he is able to cultivate the micro-organism in the serum of any other animal it would seem probable that inoculations practised upon animals of that same species would be successful. He has thus far failed to cultivate the bacilli in the blood serum of oxen and domestic fowls. Although the question of the etiology of leprosy is as yet by no means settled, the argument in favor of its contagiousness has certainly been strengthened. The bacillus has been proven to exist in every case of nodular leprosy, and although Hansen has not found it in the smooth surface of the skin, the fact shows at least his want of skill in staining. Another fact that speaks for the theory of contagiousness is its gradual decline of late, due undoubtedly, the author maintains, to the more thorough isolation that is now generally insisted on.—*Hospitals-Tidneder*, No. 32, 1883.

TUBERCULAR PERIURETHRITIS.—At the recent Congress of German naturalists and physicians, Dr. Engisch presented a paper with this title. The disease, he says, begins as an inflammatory tumor in the bulbous portion, usually as an inflammation surrounding the urethra, or involving Cowper's glands. It extends constantly, as well toward the surface, leading to perforation of the skin, as in other directions toward the urethra, prostate gland, rectum, or epididymis. The urethra is often perforated, usually at the junction of the bulbous and membranous portions, sometimes in the pendulous portion. The disease is often accompanied by fungous granulations resembling very closely those seen in tuberculosis of the articulations. It occurs in tubercular and tubercularly disposed individuals, and may arise from urethritis, specific or otherwise, injuries of the urethra or perineum, or anything which occasions or is accompanied by inflammation. The course of the disease is usually slow, yet in some cases it is quite rapid. If there is already a pulmonary affection it now progresses more quickly, and if none has existed it is now developed. Since the fungous granulations present great resistance to all modes of treatment, there is but little to be accomplished in the way of cure. New granulations are continually formed, and any attempts to close the fistula are unsuccessful. The disease requires a sufficiently long time to allow of their closure, is rendered impossible by reason of the quickly produced vesical catarrh. Hence the therapy is narrowed down to attempts at improving the general condition by means of constitutional remedies.—*Centralblatt für Chirurgie*, November 3, 1883.

SUBCUTANEOUS EMMYSEMA DURING CHILDBIRTH.—Dr. Chahbazian relates the case of a healthy woman, twenty years of age, in whom, during a violent effort made near the end of delivery, a small tumefaction was noticed just above the right clavicle. This tumor rapidly increased in size and involved the right side of the face as far as the eyelid, as well as the neck and upper part of the chest. There was neither redness nor pain,
the swelling gave a sonorous percussion sound and was crepitant on palpation. The swelling gave no inconvenience to the patient, except from its size and the fear which it inspired. The labor was speedily terminated and the tumefaction gradually subsided, having entirely disappeared at the end of a week. The point of origin of the emphysema was not clearly determined. But the author thought that it most likely arose from a rupture of some of the pulmonary vesicles in the mediastinum at a point where the lung is not covered by the pleura. In a case in which this accident occurs the patient should be encouraged to cry out, and should not be allowed to make any voluntary explosive movements.—*Bulletin de Thérapeutique*, October 30, 1883.

**THE PROPHYLACTIC VALUE OF TURPENTINE VAPOR IN INFECTIOUS DISEASES.**—Dr. H. Viland writes in the *Ugeskrift for Læger*, vol. viii., No. 8, 1883, concerning the value of oil of turpentine in the treatment and prophylaxis of diphtheria and the exanthematous diseases. He states that he has never seen any of these diseases spread from a sick child to the other members of the family when this remedy was employed. In many of his cases no isolation could be attempted, as the mother was the only female in the family and was obliged to take care of both the sick and the well, continually passing back and forth from one to the other. His method was to pour from twenty to forty drops of a mixture of equal parts of turpentine and carbolic acid into a kettle of water, which was kept simmering over a slow fire, so that the air of the sick room was constantly saturated with the odor of these two substances. He claims also that by this means a favorable influence is exerted upon the exudation in diphtheria, although it is by no means curative of the disease, and should never be relied upon to the exclusion of other remedies.

**SOME FORMS OF CIRRHOSIS OF THE LIVER.**—Hayem and Girandeau have recently published four cases of hypertrophic fatty cirrhosis, in which fatty suffrage of the hepatic parenchyma and sclerosis were associated. The sclerosis was diffuse, and of variable intensity. In one case it was markedly annular, and, contrary to what was found in a case published by Hanot, it had invaded the centre of the lobule. The hepatic parenchyma presented two noticeable lesions: fatty suffrage and pig- mentary infiltration. There also existed very pronounced anacroticism and periangiogicholysis.

Guiter (Thèse, 1883) in completing and developing the ideas of Dieulafy, proposes the title "mixed cirrhosis" for a particular variety of chronic hepatitis characterized by the association of lesions and symptoms proper to both atrophic and hypertrophic cirrhosis. The pathological anatomy of mixed cirrhosis, as one understands it, presents no especial macroscopic appearance, as the alterations found at the autopsy belong to all the forms of hepatic cirrhosis; an increased or diminished size, granular at the surface and on section, though less marked than in the confirmed period of cirrhosis as described by Lænnecc; enlarged spleen, and perhepatitis and splenitis. Pathologically this form is distinguished by the predominance of portal infiltration and parenchymatous, or interstitial, sclerosis, and the symptoms dependent on these lesions. From a histological point of view the common and dominant character of this intermediate form is the extreme irregularity which characterizes the progress of the connective hyperplasia. It is a diffuse sclerosis, at the same time annular, portal, and interlobular, with stellate and parenchymatous, with almost complete obliteration of the hepatic substance in some cases, with neo-formation of the smaller bile-ducts from a concomitant carstial angiogicholysis. The simultaneous evolution of epithelial and parenchymatous sclerosis is the great characteristic of mixed sclerosis.

The clinical characteristics are more marked. The disease often begins suddenly by the appearance of ascites, soon followed by icterus, or these symptoms may be simultaneous in their appearance. This association of these symptoms is one of the principal characteristics of the disease. The size of the liver varies greatly, it being either diminished or increased. When the disease lasts a long time, atrophy succeeds hypertrophy. More often the course is rapid; periods of amelioration are exceptional, and the patients generally die within a period of a few days or two months after going to a hospital, either of cachexia or icterus; the rapid course being readily explained by the diffusion of the lesions, and the general invasion of the hepatic parenchyma and connective tissue.

Hutin has encountered several cases, in tuberculous subjects, of cirrhotic lesions of the liver, as remarkable for their anatomical characteristics as for their clinical symptoms. There is a double lesion of the liver in these cases, connective-tissue hyperplasia having the type of hypertrophic cirrhosis, and fatty degeneration of the cells in the whole extent of the organ. The tubercular affection, which assumes a rapid course, and the hepatic affection, which presents the symptoms of a severe subacute icterus, are developed side by side. The principal symptoms, as stated by Hutinel, are: marked hepatalgia; hypertrophy of the liver, without irregularities, and a small amount of ascites and meteorism. The urine, which is rather below normal as to quantity, contains only 12 to 14 grammes of urea per diem, and is bilious or amphamorphic. There are no other symptoms, except hemorrhages—epistaxis, hemoptysis. There are also nervous phenomena, as vague delirium with generalized hyperesthesia. The patient dies comatose in two or three months. Hutinel believes that these patients generally become phthisical after an addiction to alcohol.

Hanon has admirably described four cases of atrophic cirrhosis of the liver differing from the classic type by their rapid progress and certain symptomatic peculiarities. Their duration was from two to six months, with the accompaniment of a subacute febrile process. There were marked pains in the right hypochondrium, early ascites, with oedema of both upper and lower limbs, an icteric hue of the skin, and visceral and subcutaneous hemorrhages, with profound cachexia, progressive cerebral enfeeblement, coma, and lowered temperature; in other words, the state to which the name acholia has been given—and death. The explanation of this state may be found in the state of the hepatic cells, and we have here an illustration of the general law which may be thus formulated: In cirrhoses, from a single point of view, the diagnosis depends upon the topography of the new connective-tissue formation; the prognosis, on the state of the hepatic cells. In the four cases reported by Hanot the hepatic cells were, for the most part, transformed into fat, such as is observed in acute yellow atrophy and phosphorus poisoning. It will be readily seen that the different symptoms find their interpretation in the pathological lesions.

Sevestre has reported a very interesting case of cirrhosis, with adenomatous nodules in the liver. The disease came on with digestive disturbances, and in a short time there was very marked ascites. The patient, a man forty-four years of age, was an alcoholic. The urine was small, red, and deposit of a brick-dust sediment. The liver was found, at the autopsy, to be very large, with nodules on its surface; there were also large projections, white, and resembling cancerous nodules. On the under surface there were arborescent whitish tracts from one to two millimetres in diameter, produced by filling up of the veins; on incision into these a thick, whitish liquid was poured out. The stomach was opened, and no concomitant lesions; the portal vein and its branches in the hepatic substance being obliterated by adenomatous nodule. Histological examination showed a generalized cirrhotic state, with large numbers of small encysted tumors arising from the trabeculae. The large adenomatous tubes formed cylinders partially limited by a layer of polymorphous cells. Three very similar cases
have been reported by Schüssler (Stricker's Jahrbuch, Hft. 5, 851).

Pye Smith has reported a very remarkable case of cirrhotic liver in a boy of thirteen years of age, in which the lesions of advanced cirrhosis were found both in the liver and lungs, with ulceration of the large intestine. There was no reason to believe that the subject was alcoholic or syphilitic, and the duration of the disease four years preceded the idea of tuberculosis, although the intestinal ulcer was of a tuberculous nature. H. Moore believes this to be a particular variety of cirrhosis, the lesions being preceded by pleuritis and peritonitis—these being found in this case—the inflammation extending to Glisson's capsule and producing cirrhosis.

**Extraction of a Foreign Body from the Tympanicum, with Section of the Tympanic Ring.**

The following case is related in the *Nordh Magasin for Laegeridsenboden*, vol. xii, No. 11. A little girl, aged four, while playing on the sea-shore had a stone pushed into her ear by her sister. A few days later, upon the sister's confessing her trick, the mother attempted to dislodge the stone by means of a hair-pin, but not succeeding, she took the child to several physicians, one after the other, all of whom made repeated unsuccessful attempts to extract the foreign body. It was then, and a half weeks after the accident, that the child was seen by the hospital in the charge of Dr. J. Nusse.

Examination showed numerous erosions in the external auditory canal, the outer two-thirds of which was swollen and ecchymotic, the inner third entirely denuded of skin and periosteum. The drum was gone, the tympanic ring bare, and the cavity of the tympanum filled up by the foreign body. The stone seemed to be wedged tightly in the annular part of the cavity. There was some purulent secretion from the tympanum and meatus.

The first efforts at extraction were unsuccessful, and the operation was put off till the following day to give time for the manufacture of some strong hooks. When these were procured they were slipped past the stone, but were broken off and their points left in the cavity of the ear. As the child had several times stopped breathing the chloroform was withheld and the operation again interrupted. The third attempt was successful. A very fine saw was introduced and two notches made in the tympanic ring, one directly forward and the other downward. Then the intervening section of bone, about one-fifth of an inch in length, was broken off with a chisel. The stone was now readily extracted and with it the broken hooks and ossicles. The stone measured 8.75 mm. in length, 5.5 mm. in width, and 4.75 mm. in thickness. The well-mean efforts at extraction had succeeded only in wedging it in the tympanic orifice by its largest diameter, thereby destroying the drum and the ossicles.

**Periodical Paralysis of the Motor Oculus Communis.**—Dr. Hasner relates the case of a girl, aged seventeen years, who is attacked every month upon the appearance of the menses with a paralysis of the third nerve on the left side, lasting three days and disappearing with the subsidence of the menstrual flow. It accompanied the first manifestations of puberty and has appeared with perfect regularity at every menstrual epoch since that time. The patient also suffers at the same time from lassitude and loss of appetite. The first day there is a paralysis with drooping of the upper eyelid, rotation of the eye outward and downward, dilatation of the pupil, paralysis of accommodation with unimpaired acuteness of vision, and slight exophthalmos. The second day the ptosis disappears, and on the third day the eye can be rotated downward. The pupil continues for several days and often persists for more than a week. There is nothing abnormal about the genital organs, the uterus is small and movable, the menstrual flow is rather scanty. This singular paralysis, the writer thinks, is due to some vaso motor disturbance affecting the nucleus of origin of the left motor oculi nerve. Perhaps a similar affection of the nucleus of the pneumogastric would explain the attacks of vomiting that occur coincidently with the paralysis. The author raises the question whether this paralysis, now periodical and temporary, may not in the course of time become permanent.—*Archives Générales de Médecine*, December, 1883.

**Ante-Mortem Cesarean Section.**—A patient in the hospital for the insane at Brescia was taken ill during the eighth month of pregnancy with typhus fever. While she was in *articulo mortis* the fetal heart-sounds were observed to grow feeble, and in the hope of saving the life of the child Cesarean section was per formed. The question was then propounded to several obstetricians of Italy whether such an operation were justifiable. This was the occasion of a paper read by Dr. Ottavio Morisani before the Accademica Medico-Chirurgica of Naples, and published in the *Rivista Clinica e Terapeutica* for November, 1883, in which he formulated the following conclusions: 1. If a woman dies in the course of labor the extraction of the child should be completed per via naturale. 2. In the case of a woman dying at the end of the seventh month of pregnancy, an attempt should be made to deliver the child through the natural passages; but should great resistance be met with, recourse should at once be had to Cesarean section unless there is a certainty that the fetus is dead. 3. The question whether a pelvic deformity exists which would render delivery impossible or even very difficult. 4. It is in the interest of the child to perform the operation upon a moribund woman rather than to wait until death has actually occurred. 5. In a moribund woman at term, when labor has already begun, delivery should be completed through the natural passages. 6. In the case of a moribund woman at the end of the seventh month, it may be possible to provoke labor by the usual means, although once it has begun it should be completed by the forceps. 7. If the time be too short to allow of these preparatory measures, forced delivery should be at once practised. 8. When very great difficulty is experienced in forcing the hand into the uterus, or when it is judged that extraction through the natural passages would be prejudicial to the life of the fetus, Cesarean section should be performed, followed or not by removal of the uterus and ovaries, as seems best in the opinion of those present. The operation should be performed with the same precautions as would be observed were the woman in ordinary health. 9. The rule that a moribund woman should be delivered by cesarean section at the end of the seventh month should not be allowed to pass for the cesarean section of a moribund woman at term. 10. The rule that cesarean section should not be performed in the case of a moribund woman at term, should not be allowed to pass for the cesarean section of a moribund woman at the end of the seventh month. 11. When the operation is performed by cesarean section at term, delivery should be observed in the interests of the mother not less than in those of the child.

**Primary Union of Tissues Divided by the Thermo-cautery.**—The following conclusions, based upon a large number of observations, are formulated by Dr. Reclus: 1. Tissues divided by the thermo-cautery may unite by first intestine. 2. In order that this result may be obtained, the eschar formed by the cautery should not be very thick. 3. It is necessary to guard the wound against all septic infection. The occurrence of primary union is obscured by the fact that the charred tissue is very light and is easily penetrated by the new vessels. The embryonal cells at either border insinuate themselves between the carbonized particles, meet and Anastomose, and union takes place. The adoption of antiseptic precautions is, however, essential.—*Rivista Clinica e Terapeutica*, November, 1883.

**Hereditary Polyuria.**—Dr. Weil gives the genealogy of a family in which, out of ninety-one members, twenty-three had diabetes insipidus. There were no other hereditary diseases in the family, nor of diabetes itself, which has been transmitted as an unusual old age. The ages of those affected ran all the way from two to seventy-six years. The symptoms were the ordinary ones of great thirst and increased excretion of urine.—*Deutsche Medicinische Wochenschrift*, No. 43, 1883.
PERITENТОНІЗЕ Є КУЛІТІСИ У ТЕНДО АЧІЛІСІ.

—Др. Е. Райнал зазначає кілька випадків цього об'єктивної відчуття в Archivеs Générales de Médecine для December, 1863. The disease consists of an inflammation of the tendons, which is caused by the pressure of the tympanus. The inflammation is confined to the two layers of the fascia of the leg. These two layers are united at either side, forming a sheath in which the tendon plays, but which is unprovided with any synovial membrane to facilitate the movements of the tendon. The inflammation may be either acute or chronic, and the chronic form may commence as such without showing any trace of an acute one. The subjective symptoms of the disease are pain, varying in intensity according to the degree of inflammation. It occurs only on flexion of the foot, passive extension causing no inconvenience. When suppuration occurs the pain is usually very severe. The swelling is limited to the post-malleolar gutters on either side of the tendon, and never appears anterior to the joint. There is no redness of the skin as long as the inflammation is confined between the two layers of fascia. The local temperature is more or less elevated according to the degree of inflammation. The condition is to be distinguished from inflammation, sprain, and hyperesthesia of the ankle-joint, as well as from subcutaneous cellu- litis. The distinctive points are the localization of the swelling, absence of pain in extension of the foot, and absence of redness of the skin. The prognosis as regards a speedy cure is not favorable. Treatment consists in rest, at least in the early stages, local abstraction of blood, anodyne poultices, and inunction with mercurial or belladonna ointment. In the chronic stage, vesication, incisions, and light cæterization are of value. Care should be taken to avoid pressure over the tendo Achillae, and elastic gaiters especially should never be worn.

TRISMUS NASCENTIUM.—In a paper on this subject in The American Journal of the Medical Sciences for January, 1884, Dr. J. F. Hartigan supports the theory advanced by the late Dr. Maris Sims, that the symptoms are due to the effects of mechanical pressure on the brain by displacement of the occipital or parietal bones as the result of an effort of swallowing, and may be relieved simply by rectifying this abnormal displacement, often by change of position in lying alone.

STERILITY SUCCESSFULLY TREATED BY THE UTERINE BOUGIE.—Undoubtedly the most numerous cases of sterility are due either to a simple contraction of the cervical canal, or to such contraction complicated with one of the various flexions or versions of the uterus; and although treatment of the former by dilatation and the latter by pessaries has long been in vogue, pathological variations of gynaecology have shown their disadvantages innumerable. Convinced that pessaries in women who have not borne children frequently give rise to irritation or inflammation, thereby adding another impediment to conception, Dr. E. A. Spooner, in The American Journal of the Medical Sciences for January, 1884, states that he has long since abandoned their use in the treatment of these cases, employing a bougie with support for patients requiring relief from prolapse or other displacements without regard to the question of conception. Fortunately many cases of flexions or versions are amenable to the treatment of the uterine bougie, and when occurring as complications of a partial atresia of the cervical canal, the correction is readily made coincident with the dilatation, and he has been surprised at the ease with which long-existing and extreme flexions have yielded to treatment by bougies, which he describes in detail, and illustrates with the histories of several successful cases selected from his note-book.

THE ACTION OF TARTRATE OF CHINOLINE.—From a series of experimental investigations concerning the action of tartrate of chinoline, Dr. Sudeikin (Frách) describes the following: 1. Chinoline is one of the drugs which act tonically both on cold-blooded and warm-blooded animals. [Frogs die in two to three hours from two grains of chinoline, rabbits in about twenty-four hours from eight grains.] 2. It acts chiefly on the nerve-centres, and mainly on the spinal-cord and medulla oblongata (paralyses the reflex activity). 3. It acts, also, to paralyze the excitations of the motor nerves. It paralyses the excito-motor nerves of the heart. 5. It powerfully lowers the temperature of the body (e., after the administration of twelve grains to a rabbit the temperature in two and a half hours fell from 38.3° C. to 32.9°, and in nine and a half hours to 29.2°). GLOBULINURIA IN ACUTE BRIGHT'S DISEASE.—A case of acute nephritis is reported by Herr Werner, of Heidelberg, as occurring in Professor Dr. H. Kühne, a child, aged five years and a half, who developed symptoms of the disease after exposure to wet, five days before his admission into hospital. There was only a little oedema of the eyelids, together with signs of diffuse bronchial catarrh on admission, but general dropsy rapidly supervened, and death occurred from suppression of urine five days afterward. What renders the case remarkable was that the urine only contained globulin, and never serum-albumen, although repeatedly examined, amongst others by Kühne. The characters of the urine were its high color, cloudiness, and moderate deposit, but no blood. Slight turbidity appeared on boiling with nitric acid, and also with acetic acid, clearing up on immersion with silver nitrate, and a white precipitate was obtained in the filtrate on the addition of nitric acid. Fatty epithelial and granular casts were found. The writer points out that hitherto globulin has never been met with in urine unless in company with serum-albumen; and quotes the statement of Senator to the effect that the quantity of globulin is most abundant in cases of renal disease, next most abundant in acute nephritis, and least in the chronic diffuse form, although much albuminuria may be present. The same author also suggested that the globulin may be derived not only from the blood, but also from the morbid changes undergone by the renal epithelium, and Herr Werner thinks his case proves the possibility of its being solely derived from the latter source. He interprets his case, then, as one in which the renal epithelium was principally affected, which speedily and widely fell into a necrotic condition, as evidenced by the tube casts, and that this necrotic cell protoplasm was the source of the globulin. The idea is, to say the least, ingenious, and it is most unfortunate that no post-mortem examination was made. It should be added that the child had previously been in good health, and had never had scarlet fever.—London Lancet, December 8, 1883.

THE ACTION OF INFUSED BEVERAGES ON Peptic INDURATION.—Dr. James Fraser (Edin. Chir. and Path Journ., November 10, 1883) has undertaken a series of experiments to determine the effect of the ordinary infused beverages, tea, coffee, and cocoa, on the digestion of albumen. He finds that all retard digestion, except in four instances, viz., ham and white of egg with coffee, and fish with cocoa and with cocoa. Salt meats are less retarded in digestion than fresh. The retardation is greatest with cocoa, less so with tea, and least with coffee. Tea causes flatulence. Cream and sugar reduce the retarding effect of tea, but increase that of cocoa. He recommends as a practical conclusion that albuminoids, especially fresh meat, should not be taken with infused beverages, and therefore condemn "meat-tea."

COLD DOUCHE IN INTESTINAL COLIC.—Dr. Teplashesn (Frách) elucidates the pain-soothing effect of cold irrigations applied to the belly in cases of abdominal colic. The purpose is obtained by directing to the painful region a thin stream of cold water from a teapot lifted a foot or a foot and a half from the body. The author saw rapid relief, even to the most excruciating pains, after the internal administration of opium and subcutaneous injections of morphia had failed.
THE MICROBE OF PNEUMONIA.

It was long ago suspected that pneumonia was not a purely local disease, consisting in a non-specific inflammation of a greater or less portion of one or both lungs. And even before the recent investigations concerning tuberculosis lent weight to the supposition that other diseases might also be of bacterial origin, there were not wanting authors who strongly inclined to a belief in the possibly infectious nature of pneumonia. Not long ago Friedländer, in a communication addressed to the Clinical Society of Berlin, described a micrococcus which he had found in the alveolar exudation of pneumonia, and quite recently Talamon presented to the Anatomical Society of Paris a résumé of his investigations on the same subject. The results obtained by the two observers mentioned were not altogether satisfactory, since the micrococci found by them do not seem to have been identical. Possibly, however, the different appearances presented may be due to the difference in their respective methods of examination. On the other hand, it is worthy of note that Talamon did not always find the same organism, nor were his inoculations invariably followed by pneumonia, pleurisy or other inflammations sometimes resulting. In view of these discrepancies he did not insist too strongly upon the infectious nature of pneumonia, nor yet upon its direct causal relation to a specific micro-organism.

The coccus which he found most frequently in pneumonia, which he was able to reproduce by cultivation, and which, moreover, when inoculated into healthy rabbits, seemed in many instances to be the immediate cause of a true pneumonia, he described as of an ellipsoid shape, tapering down to a thread at one end, thus resembling in general a grain of barley. Its size was variable, averaging in the pneumatic exudation about two micromillimetres in length, and one in width at its largest transverse diameter. When cultivated outside of the body, it occasionally attained a size of 3 or 4 micromillimetres in length, and 1½ to 2 in width. It was sometimes single, though generally he found two united in the form of a diplococcus. There were often chains of three or four of the ellipsoid bodies united end to end, and sometimes in the culture fluid he found eight or ten links, always preserving their barley-grain shape. All were perfectly motionless. They were deeply stained by methyl-aniline violet, but became thereby somewhat changed in outline, approaching more nearly a spherical shape. In addition to this peculiar organism he often found zoölogically masses of round bodies, from the surface of which were becoming detached some of the ellipsoid cocci. Friedländer had never found these zoölogically masses in the pneumatic exudation. Talamon obtained the exudative matter directly from the pulmonary tissue by means of a Pravaz syringe, thus avoiding any contamination with atmospheric bacteria. He was never successful in isolating the microbe in the sputa. He found it in the blood in a very few instances, and then only immediately before death.

Inoculations with the cultivated organism were followed by negative results in dogs, but in rabbits were uniformly productive of pneumonia, that is to say when the injections were made directly into the pulmonary tissues. But when the injections were practised under the skin of the thigh they were attended by no results, not even a local abscess being formed. The disease produced in the successful cases was a true lobar pneumonia, and not the form that is usually found in artificial septicemia of rabbits. In a few instances the lungs were found healthy, but the pleura and pericardium were the seat of a fibrino-serous inflammation. In these cases it is supposable that the point of the syringe did not enter the lungs, and that the fluid escaped into the pleural cavity.

Finally, in two cases of pneumonia complicated with pleurisy and peri- and endocarditis, Talamon found an organism of different form, arranged in long chains of ten to twenty round bodies, very unlike the micrococci described above. It was reproduced in the same form by cultivation. It was found in the same individuals after death in the blood, the pericardium and the peritoneum, which was also the seat of a fibrinous inflammation. Inoculations with these organisms were followed by a pneumonia precisely similar to that consequent upon the injection of the other variety. Notwithstanding the unexplained discrepancies in the results hitherto obtained by investigators into the nature of pneumonia, M. Talamon felt justified in maintaining, with some reservations, that the disease is of an infectious nature, and caused by the multiplication within the lung of a specific microbe. He regards pneumonia, however, as a primarily local affection capable of generalization, and not as a general disease with local pulmonary determinations.

The investigations here alluded to will not definitely seal the fate of pneumonia to the extent of placing it irrevocably within the ranks of the bacterial infectious diseases. Nevertheless, it is to be admitted that the presumption in favor of so regarding it is considerably stronger with the positive evidence which these most recent investigations afford, than it ever could have been by merely reasoning from analogies and theoretical data. The present drift of experimental pathology is all in the direction of mycology, a field richer in promise than in accomplished harvest. It will not do, however, for pathology to cut loose entirely from clinical medicine. So with typical pneumonia, the natural history of which is clinically complete and perfect; we will have to know much more about its cocci before we can exchange our present opinion concerning its essential nature, for one that puts it in the same category with the specific inflammations of infectious origin.
THE NEW URINARY TESTS.

Medical literature in the past six months has become very rich as regards the subject of urinary tests. There have been brought forward the following, as tests for albumen:

Picric acid, by Dr. George Johnson; acidulated brine, by Dr. Roberts; potassium-mercuric iodide, by Dr. Stephens; sodium tungstate, by Dr. Oliver; potassium ferrocyanide and citric acid, by Dr. Pavy; chloride of sodium and chloride of iron, by Dr. Halsam.

As new tests for sugar, we have had presented the diazobenzol sulphuric acid test, by Pentzold; the picric acid test, by Dr. Johnson, and the indigo test by Dr. Geo. Oliver.

Certainly here are sufficient means to confuse the practitioner in his labors to discover the nephritic disturbances of his patients. So far as the tests for albumen go, however, we can say at once that none of them exceeds in value, and scarcely in delicacy, the careful use of nitric acid and heat. Yet while this is true, we are inclined to think that some of the tests will prove useful because of their greater convenience and more striking reactions.

In testing urine for serum-albumen, there are a number of things which must be borne in mind. Urine contains, or may contain, a number of albuminous bodies besides serum-albumen, viz., peptone, parapetone, globulin, paraglobulin, fibrin, and mucin. Having got an albuminous precipitate, therefore, by some reagent, it is still necessary to learn what form is present. Mucin can be, in large part, removed by filtration. Fibrin is rarely present except in chylous urine or in haematuria. Globulin and paraglobulin are probably never, or very rarely present, except when there is also serum-albumen. Peptone and parapetone, however, do appear in the urine independently of other proteids. Their precipitate, however, can be readily distinguished by its dissolving with heat. Hence, although the problem of differentiating serum-albumen appears to be complex, it is practically not difficult.

The objections which have been raised to the heat and nitric acid test are those of inconvenience, lack of delicacy, and of the need of caution to avoid any source of error. If the urine be slightly acid or slightly alkaline, and but little albumen is present, heat will not cause a precipitate. If the urine be alkaline, heat may produce a cloud of earthy phosphates. Nitric acid, if added in very small amount, may change the albumen (if that is also in small amount) into sytonin, which is not thrown down by heat or acid, but only by neutralizing the fluid. Nitric acid may also throw down a cloud of urates. These dangers, which apply only to cases where there is little albumen present, can all be obviated by using Heller's method, viz., pouring the nitric acid into a test-tube, then letting the urine flow upon it, and carefully boiling, if there is a white zone produced.

Of the substitutes advanced for the above method, picric and citric acids, sodium tungstate and citric acid, and potassium-mercuric iodide have received the most approval.

To apply the picric acid test, the urine must be first slightly acidulated with citric acid, since if alkaline the picric solution might throw down urates. A saturated solution of picric acid is then added in amount, when a white cloud is formed, if serum-albumen or peptone be present. To exclude peptones the urine must be boiled. It will be seen that the application of this method is not so extremely simple as was at first claimed. It has also been shown that picric acid produces a precipitate when the patient has been taking quinine. It may yet be found that it will show the presence of other drugs in the urine.

Sodium tungstate is a very cheap substance and a cleaner one to use than picric acid. Oliver recommends equal parts of solutions of the sodium salt (t-.4), citric acid (10-6) and water. This when added to the albuminous urine produces a cloudy precipitate.

It involves something of a refinement to say which of the above is the more delicate. The potassium-mercuric-iodide test has no more special advantage over others. Hassam's test consists in adding to the suspected urine several drops of a solution of chlorid of sodium. Then a solution of chloride of iron (liq. ferri perchlorid.) is carefully poured down the test-tube, when if albumen is present a white ring will be seen. This ring, however, may be composed of phosphates, therefore a little citric acid must be added.

The test suggested by Pavy, of ferrocyanide of potassium and citric acid, is the common one for proteid bodies of all kinds, and is not suitable for distinguishing serum-albumen.

The introduction of the tests thus enumerated will no doubt prove of value, since minute amounts of albumen can be detected with less scrupulous care. We cannot agree with Dr. Johnson, that the presence of albumen in such amount always indicates a serious pathological condition, and practitioners will err if, frightened by an unexpected precipitate, they treat patients at once as though there was an important lesion of the kidney.

We would say, in conclusion, that the picric acid test is likely to become the more popular, because the same reagent can be used as a test for sugar. It can be carried and used in the form of a powder. Citric acid should be carried with it either in the form of crystals or in that of citric acid papers, as suggested by Dr. Oliver.

ENGLISH MEDICAL JOURNALS.

The English are the greatest printers and the best journalists in the world. The ability and skill which they show in their daily papers is evidenced also in medical journalism. In the purely journalistic and technical part of the work of editing and publishing medical periodicals, the profession of England is ahead of that of any other country. Nowhere else are there weekly journals of forty to sixty pages' length, more than half of which is perhaps the product of staff work. In the amount of editorial and reportorial work expended, America alone can compete with England. In these particular branches the former country is now pressing closely upon the latter.

A characteristic of English journalistic work is the literary skill displayed; the editorial writing is generally careful and often forcible, while the editors are remarkably apt in turning every-day events into "material," and in throwing a medical—not to say "bony"—light upon
them. We are obliged to say, that undoubtedly another not so admirable characteristic of English editorial work, is the union of a certain heaviness of style with triviality of subject, the result being a kind of medical bathos—which is the hypnotic quality in leading articles.

If as regards journalistic skill the English are ahead, this does not imply that medically or scientifically the same is the case. The English medical journals in respect to original and scientific work are far behind Germany, and hardly abreast of France. Along with frequent contributions of practical value, there is a vast deal of padding. Addresses which are diffuse and commonplace, hospital and society work which is without interest or suggestiveness, medico-parliamentary and sanitary reports fill up many pages in our most admirable contemporaries.

There is no such endemic of journalism in England as exists in Germany, France, and America. The few great London weeklies attempt to cover the whole range of medicine, making special journals almost unnecessary. There are quarterly journals devoted to mental and nervous diseases, and there is a journal of physiology. Ophthalmology is represented by a monthly; but so far as we are aware this ends the list of specialist's journals, even gynaeology being without an organ. Dublin, Edinburgh, Glasgow, Birmingham, Bristol, Liverpool, each has its local monthly.

The strength of journalistic effort is, therefore, concentrated upon the weeklies, and even these can be counted upon the fingers.

The Lancet undoubtedly still retains its pre-eminence as the leading exponent of English medical journalism. No other journal apparently expends quite so much careful attention upon, or enlists so much ability in, its editorial work. The Lancet aims for position and influence with the general public as well as with the profession. It has undoubtedly helped to give dignity and force to medical opinion. We venture the criticism, however, that it goes too far at times in peddling out gratuitous sanitary instructions to the laity as regards every conceivable social custom or individual habit. The Lancet, perhaps, even more than its compeers, exhibits an extraordinary facility in discovering the medical significance of contemporaneous incidents, and can write profoundly and medically upon all things from the war in Egypt to the accouchement of a duchess.

The British Medical Journal is truly a wonderful periodical, and is constantly increasing its circulation. Its size is a little appalling, and there is a great deal in it regarding sanitation, medico-parliamentary and branch-meeting affairs, which are not very interesting outside of England. The Journal is doing an effective work in consolidating the medical profession and increasing its political influence.

The Medical Press and Circular, which we believe is published in Dublin as well as in London, though, somewhat smaller, is not inferior to the other weeklies in the editorial ability which it displays.

### SUB-UMBILICAL PERITONITIS.

The peritoneum is often divided, for convenience of description, into two parts, a superior or supra-umbilical, and an inferior or sub-umbilical. An inflammation may be limited to one of these parts so that, as proposed by Beau, we may speak of a supra-umbilical or a sub-umbilical peritonitis. It is generally admitted that one of the chief sources of danger in a case of acute peritonitis is the extension of the inflammation to the superior portion of the membrane. It is then of some practical importance to differentiate between these two forms of localized peritonitis. In a paper on this subject in the Archives Générales de Médecine for December, 1883, Dr. Alphonse Goix summarizes his views as follows: Acute sub-umbilical peritonitis is manifested clinically: 1, by those general symptoms common to every attack of acute peritonitis; 2, by local phenomena pertaining to this form alone, viz., a superficial pain limited exactly to the lower half of the abdomen, retention of urine, and meteorism; 3, by a negative sign of very great importance, viz., a normal diaphragmatic respiration. Acute sub-umbilical peritonitis is distinguished from acute perityphilitis by the absence of tumefaction about the cecum, and from sub-peritoneal inflammation by the preservation, during the entire course of the disease, of the mobility of the skin over the subjacent tissues. In this latter disease the subcutaneous connective tissues are always secondarily involved and the skin loses its mobility. Since, as already stated, the chief danger in peritonitis is in the extension of the inflammation to the supra-umbilical portion, it is always important to watch with care the respiratory rhythm and the diaphragmatic movements.

### ARTIFICIAL CULTIVATION OF VACCINE VIRUS.

Dr. C. Quist, a physician of Helsingfors, Russia, announces, in the St. Petersbürger Medicinische Wochen-schrift, that he has discovered a method by which vaccine virus can be cultivated in the laboratory. His claim, if true, would render vaccine farms superfluous, since all our virus could be grown in a watch-glass. It will, therefore, be examined with much interest.

Dr. Quist, by cultivating the micrococci of the vaccine lymph found that they developed into bacilli, which in turn produced micrococci again. After many experiments he found that the two things necessary for growth were oxygen and a proper culture-fluid. The vaccine bacterium is, he says, "an exquisite aerobium." The best culture-fluid he found to be egg or serum albumen, to which is added glycerine (to prevent desiccation) and a little carbonate of lime.

The following is one of the several formulæ which were used:

<table>
<thead>
<tr>
<th>B. Blood serum</th>
<th>1 part</th>
</tr>
</thead>
<tbody>
<tr>
<td>Glycerine</td>
<td>1 &quot;</td>
</tr>
<tr>
<td>Aque destill.</td>
<td>1 &quot;</td>
</tr>
<tr>
<td>Calci carbonat.</td>
<td>&quot;  &quot;</td>
</tr>
</tbody>
</table>

This fluid is sterilized by keeping it at a temperature of 60° C. It is then spread upon a glass plate, a drop of vaccine lymph is mixed with it, and the whole is covered with a glass bell. The preparation is thus kept for a number of days. In six to ten days the surface is covered with the vaccine organisms. A little of this can be removed and inoculated with the result, according to Dr. Quist, of producing a perfect vaccine pustule. Our experimenter has found, also, that one inoculation of this cultivated virus produces immunity against a second. He
does not, however, yet give evidence to show that these inoculations prevent small-pox.

It appears from reading the account of Quist's experiments that they were carefully conducted. The obvious criticism, however, is that they may only show that vaccine lymph can be largely diluted and yet retain its potency.

ON DIRT AS "MATTER OUT OF PLACE."
The physicist who tersely defined dirt as "matter out of place," showed that he was possessed of the insight of a moralist as well as philosopher. We assuredly know no apter designation for a certain class of advertisements which flout their nauseous shapes so vauntingly in the columns of our religious contemporaries. We regret to say that our evangelical colleagues still parade before the eyes of the world their painfully practical exegesis of the text "He that is filthy, let him be filthy still." These brethren yet cling to a rôle which grates on the sensibilities of many of their readers, much as the conduct of the sporting clergyman, who rushed from the hounds to service with his surplice thrown hastily over his pink coat, must have wounded the *amour propre* of many a sharp-sighted parishioner. His muddy boots peeped from beneath his gown and his reeking hands smirched the good book as he turned the leaves.

Yes, we reverently and expectantly settle down in our pew as you enter the pulpit and a few premonitory qualms of our modicum of conscience play about our heart-strings. A sense of our own unworthiness begins to assert itself. The pinched features of the poor widow yonder in the corner makes our hand twitch in an unwonted way about our vest pocket. In short, a mood at once tender, restful, and forgiving; a kindly, earnest, thoughtful calm has come upon us unawares. "Dearly beloved," comes the plea of the minister, "Beware of the foxes, the little foxes, which gnaw the vines—" Hold on there! That graceful gesture brought to light a gleam of pink beneath the lawn sleeve. Upon my word, I see his foul boots. A fine one, you, to tell me to "be aware of foxes." Unclean! unclean! *Vanitas vanitatum*. All is vanity, even the voice of the preacher.

Dear brethren of the religious press, do you not recognize the truth of the physicist's definition, and are you so deplorably color-blind that the character of the matter so wofully out of place in your paper creates the impression of spotless purity upon your moral retinas? Do you see no shameful incongruity in a teacher pointing with one hand to the straight and narrow path of godliness, and with the other to the haunts of those who display devices for eluding the wages of sin? In one column you lament the flood of pernicious literature which is debauching the innocence of youth; you lend your influence in the next to introduce in Christian homes a "specific for nervous prostration, spermatorrhoea, and alcoholism."

We have been led to allude to the subject of boots. You are probably familiar with the old adage about "the boot on the other leg." Just suppose you change your "rights and lefts" for a moment, and see if they pinch. It may help that defect in your vision, so we will extend our professional assistance.

You have probably not been called upon to review a little book, lately translated from the French, entitled, "The Life of Sarah Barnum, by Marie Columbier." There is such a book, however, as you may find on inquiry at any station of the Elevated road or at the bookstores. Plainly, it is a disgusting recital of the life of one dissolute woman from the pen of another. It is worse than dirt, it is filth, and report says has proved to be too highly spiced even for the prurient taste of the Parisian monde. The publishers have seen no incongruity in advertising a standard work on the inside pages of the cover. Here we find commendatory extracts (about the *standard work*) from various papers, among which is to be seen the names of several of our religious contemporaries which are noted for wide influence as well as wide advertising columns. Prominent among these is our old friend, the *Watchman*, who must find the cover of the "Life of Sarah Barnum" a disagreeable substitute for the walls of Zion.

Did we hear you speak, gentlemen? We are glad to see you lift your hands in righteous indignation and cover your faces from very shame. Yes, we agree with you that for those who love the honor of their high calling such a combination as the one mentioned must be painful in the extreme. Shame on those who would scatter dirty pages and think to excuse themselves by pointing to clean covers! Aye, brethren, and shame on those who scatter truth in dirty covers!

What did you say? *O tempora! O mores! O—ouch! It pinches, does it? No wonder, the boot is on the other leg.*

**News of the Week.**

A COLORIST IN BACILLI.—Another heated discussion recently occurred at the Académie de Médecine on the subject of the tubercle bacillus. M. Germain Séé charged M. Colin, who denied the specific character of the bacilli, with being ignorant of the technique of their study, and with having no clinical experience. "I may not be," replied Colin, "quite enough of a clinician to suit M. Germain Séé, but I am not, like him, a coloriste en bacilles." M. Colin claimed that the bacilli only accompanied the specific virus.

A "YANKEE," A "COCA-NUT," AND A "RED-SKIN."—Some time ago we wrote an editorial article upon French medical journals, in which we ventured to state some things that were, and some that were not, flattering to Gallic vanity. One of these journals, which by some extraordinary oversight we failed to mention as representative in character, viz., *Le Moniteur de la Politechnique*, has taken great offence, and in a two-column article brands the hatchet in a most amusing fashion. It calls *The Medical Record* "a coca-nut" and a "Yankee," and finally concludes by saying, "You are without education, without wit, without intelligence, in fine you are a 'red-skin!'" It is rather hard to be called a "coca-nut" and a "red-skin" all in one article; but we have always said that French medical editors were witty men, and so we can forgive our amiable contemporary *Le Moniteur*, etc., now.

MEDICAL REFORM IN OHIO.—In a series of vigorous editorials the *Columbus Medical Journal* is urging the cause of higher medical education. It urges the estab-
lishment of a State Medical Board of Examiners, and higher requirements as regards preliminary education. It also criticizes the new college in Toledo as not doing what its announcements claim.

**Mixed Examining Boards.**—Our contemporary the *Boston Medical and Surgical Journal* nods its Homeric head. It announces that the New York County Medical Society (and there is only one such) has adopted a resolution urging the passage of a pending bill establishing a State Medical Board of Examiners composed of regulars, eclectics, and homoeopaths. This action it impliedly asserts as being non-progressive. The County Society did not endorse this bill; but if it had, it would not have endorsed a new measure. The very active Illinois Health Board, which practically has the licensing power, and whose work our contemporary has, we believe, highly praised, is a mixed board. So also are the examining boards in several States where such organizations exist.

**A Bill to Establish a State Board of Health in Ohio** is again before the Legislature.

**The Veterinary Department of the University of Pennsylvania** has been organized. The faculty consists chiefly of the professors in the medical department, Dr. R. D. Huidekoper being the only V.S. announced on the programme.

**The Philadelphia Clinical Society** is the title now taken by the Northern Medical Association of Philadelphia, which has recently reorganized. Dr. Henry Beates, Jr., is President; Dr. G. E. Richardson, Recording Secretary.

Dr. Julius Wise has taken the place of Dr. D. C. Gamble, as St. Louis editor of the *Weekly Medical Review*.

**Another Royal Doctor.**—Another member of the royal family of Bavaria, Prince Ludwig Ferdinand, has been made a doctor of medicine, *honoris causa*. "Dr. Ferdinand" submitted to the Munich Faculty a thesis entitled "The Tongue: A Study in Comparative Anatomy," which is said to be a very fine piece of original work. A deputation, consisting of Professors v. Voit, Rüdinger, Kupfer, and Petenkofer, presented the Prince with his diploma.

**Medical Instruction to Women in Bombay.**—A set of rules regulating the mode in which medical instruction is to be imparted to women in local colleges, and setting forth the terms upon which females are to be admitted to medical degrees, has been published under the authority of the Bombay Government.

**A Poetical Suicide.**—A German convict in Chicago committed suicide recently, and before doing so left a commemorative rhyme, which runs as follows:

"Here's a recipe for a popular suicide:
Take twenty grans of potassium cyanide."

A fellow convict a few days later took the recipe, which was distributed freely among the prisoners. We cannot deny that it is a good one.

**Fear of Female Students in Russia.**—All the female medical students in St. Petersburg—a class from which many redoubtable members of the Nihilist party have emanated—have just been compelled to take up their residence in a large boarding establishment, provided by the authorities, under the superintendence of Princess Shakhafsky, instead of being free, as heretofore, to live where they please. They are to pay ten rubles per month for board and lodging, and be at home before nine o'clock in the evening, under penalty of exclusion from the medical course.

**Advertising through the Medium of Medical Colleges.**—The St. Louis Medical Society has adopted the following resolutions: "Whereas, advertising by physicians is not considered respectable, and is strictly forbidden by the Code of the American Medical Association; whereas, medical schools and colleges have from time immemorial arrogated to themselves the right not only to advertise the schools and colleges, but also the names of every individual connected with them, the chairs which they fill, and even their residences, etc.; whereas, a wrong in an individual cannot possibly be a right in an association; therefore, resolved, 1. That the professors and lecturers in medical schools and colleges are requested to refrain from letting their names appear in the circulars, prospectuses, and cards; 2. That the American Medical Association be respectfully petitioned to deny representation to all medical colleges which parade the names of the professors in their circulars and act contrary to the spirit of this rule."

We recall a story current in this city of a leading college professor, and defender of the National Code, who had been lending his name, with its collegiate appendages, to a prominent mineral-water firm. He received a call from a censor, who showed him the advertisement and made a protest. The censor was simply requested to leave the office and attend to his own business. This he did, for the professor was a great man. Certain less powerful men, however, were disciplined without any trouble.

**Bichloride as an Antiseptic.**—The item "Bichloride as an Antiseptic," on page 167 of the issue of *The Medical Record* for February 9, 1884, is incorrect in stating that the "combination was first suggested by C. Amend, a chemist, of this city." It was proposed by Mr. Chas. Am. Ende, chemist, of Hoboken, N. J.

**Hemorrhage in the Pons.**—Dr. Brandt, of Brooklyn, writes: "Be kind enough to recognize in next *Medical Record* the typographical error on page 167, in my reply to Dr. Lyman's article on 'Apoplexy' (*Medical Record* of February 9, 1884). In the third line from bottom of page it should read 'pontine' (hemorrhage in pons Varolii) and not 'positive' as it reads now. The full force of the criticism is lost as it now stands."

**A Bill to Restore the Quarantine Powers of the National Board of Health.**—The House of Representatives of the National Board of Health has been introduced into the House by Mr. Young, of Tennessee. The *Sanitary Engineer* says of it: On comparing it with the Quarantine Act of 1879, which expired by limitation last year, and which this bill is intended to replace, we find that the present bill omits all penalties, and requires nothing in particular of vessels coming to this country from infected ports. The Board is to aid State and Municipal Boards in the execution of their rules—i.e., they are to be conciliated by saying to them, "Do whatever you
like, only let us have the privilege of paying some of your inspectors," etc. This arrangement ought to secure the Southern vote, but we fear it will not conciliate Dr. Joseph Jones, of the New Orleans Board, nor will it meet the approval of the Treasury Department. It would seem that the Board is either satisfied with its present organization and relations to other departments of the Government, or thinks it not worth while to attempt to make any change. In either case the prospect does not appear to us to be very satisfactory.

A MODEST PROPOSITION.—The State Homoeopathic Society, at its meeting in Albany last week, adopted a memorial to the Legislature expressing its disapproval of all medical bills now pending, and favoring the appointment of a Board of Examiners, composed of three regulars, three homoeopathists, and three eclectics.

DISCUSSION ON CONCUSION OF THE SPINE.—The New York Medico-Legal Society, after three trials, got a sufficient number of persons together last week to discuss a paper by Dr. J. G. Johnston, of Brooklyn, on "Concussion of the Spine in Railway Injuries," read last December.

DR. CHARLES M. FORD, a prominent physician of Washington, died on February 15th, at his residence on Capitol Hill. Dr. Ford was about forty-three years of age, and was a native of New York. He studied his profession in Philadelphia, and after being graduated, entered the Union Army as a surgeon attached to a New York regiment.

A REQUEST BY THE LATE DR. BEVERLY LIVINGSTON.—The late Dr. Beverly Livingston, of this city, a graduate of the Yale Sheffield Scientific School in 1874, requested before his death, last year, that his scientific collections and certain other property should be given to the school. His wishes have just been carried out by his father, and the institution has been enriched by a large number of microscopic slides and other physiological specimens, and its permanent fund has been increased by $3,000. This is the first legacy received by the Scientific School from one of its graduates.

THE TRICHINOSIS QUESTION IN FRANCE.—The commission appointed to investigate the epidemic of trichinosis at Emerseleben, consisting of MM. Graucher and Brourdard, made a report to the Académie de Medicin, in which they stated that the epidemic in question was of German origin, and not due to imported American pork. They stated also that the gravity of the disease diminished in proportion as the pork was mixed with other food and in proportion to the time that the meat had been preserved after the killing of the animal.

PHYSICIANS' MUTUAL AID ASSOCIATION.—The annual report of this organization shows that it is in a prosperous condition. "The benevolent feature of the Association is its chief recommendation. The permanent fund now exceeds the constitutional limit required to make its interest available for charitable objects. From this income the widows and orphans of a deceased member may be aided, and any worthy member assisted, as has already been done in several instances." The above is a quotation from the report and is well calculated to encourage a practical sympathy and support of the society by medical men.

This is a scholarly and well-handled essay, in which the doctrines of evolution are most ingeniously and cleverly applied to substantiate and explain the germ theory of disease. It is forcible and suggestive throughout, and whether one agrees personally with the author's conclusions or not, we all must be impressed that here is a careful and accurate observer, whose views must command respect if not conviction, and whose method of investigation in a particularly abstruse but rich vein of thought must gain the generous sympathy and approval of the profession at large. Mr. Millican's compact monograph is a most valuable contribution to our current literature from this very fact, for it is by just such conscientious and skilful medical study that our profession is saved from the pitfalls. It is by no means unlikely that our author's labor has brought him to the threshold of one of nature's most subtle and stupendous secrets, fraught with an importance to humanity which our present limited knowledge can but imperfectly appreciate.

The outbreak of cholera here reported occurred shortly after the establishment of a cholera convalescent camp, some hundred and fifty miles distant at Murree. Aside from the fact that the whole subject has of late acquired new interest, an intelligent and authoritative résumé of a typical outbreak of the disease must always be suggestive and command attention. Few points have escaped Dr. Jessop's careful investigation, and he has given us a straightforward, eminently business-like report. The reader recognizes the military mind, not only in the simlicity and exactness of the "war-map" diagrams, but in the promptness, exactness, and method with which each point is taken up and discussed.

The author speaks very favorably of the use of the hypodermic injection of chloral as the most beneficial method of bringing the stage of collapse to an end by the control of the cramp symptoms. He lays particular stress on posture as an auxiliary in the treatment, i.e., the patient's head must be kept high and his feet low; in other words, the position is one of semi-reclination. Accordingly he advocates a reclining-chair in place of the bed. The rationale of this last is essentially the same as that of a change of posture in the treatment of ordinary pulmonary congestion, and Dr. Jessop considers it of the highest importance.

NOTE-BOOK ON POST-MORTEM EXAMINATIONS. By BYROM BRAWMELL, M.D., F.R.C.P., Pathologist to the Royal Infirmary, Edinburgh, etc., etc. Edinburgh: Maclachlan Stewart. 1883.

This note-book is presented by the author with the view of facilitating the complete and systematic method of performing and recording post-mortem examinations. It will be found to be not only an excellent assistant to students attending the post-mortem, but in hospital service its value is apparent as well as in private practice, especially in medical-legal cases. The order adopted in making the examinations is, for the most part, that recommended by Virchow. The book contains headings for fifteen complete and twenty-three incomplete examinations, for twelve cases in which the examination is limited to the cavities of the thorax and abdomen, fol-
lowed by headings for seven cases where the cavities of the thorax, abdomen, and cranium respectively are examined. An index is also provided.

In these two sumptuous volumes, it may truly be said that Dr. Ross has included not only all the essential facts connected with the morphology of the brain and spinal cord, but also a host of data bearing upon the essential anatomy and physiology of the subject.

The work is copiously illustrated by a large number of excellent cuts, which serve to fix the prominent clinical and pathological features in the mind of the reader, thus adding plasticity and clearness to his conceptions of the entire subject.

The anatomical and physiological introduction, which precedes the section of the work devoted to diseases of the medulla and spinal cord, is especially worthy of commendation, on account of the clearness, comprehensiveness, and thoroughness with which this intricate chapter in the physiology is treated. And the same may be said of the section on the central anatomy and physiology.

In many works on diseases of the brain or cord, this portion of the subject has been handled with so little dexterity that the practical physician, being unable to penetrate the maze of ambiguity, has involuntarily conceived a positive aversion for neurological science.

Dr. Ross, on the contrary, deserves to be congratulated upon the success with which he not only conceives, but also conveys ideas, even upon themes apparently involved in a high degree of complexity.

Having thoroughly perused these preliminary chapters, the professional reader will encounter little else but pleasure during the remainder of his literary journey. Central and peripheral nervous system—diseases of the medulla oblongata and spinal cord, are now easily understood; and the physician finds that he has penetrated into the apparently impenetrable fastnesses of clinical neurology, almost before he is aware that he has crossed the threshold of scientific inquest.

To this, the second edition of his able work on the "Diseases of the Nervous System," Dr. Ross has added a large number of historical references, besides amplifying and re-writing many of the chapters. It is hardly necessary to add that this thorough revision has greatly conduced to the value of the work, and it may safely be predicted that these two volumes are destined to maintain their place in neurological literature.

A copious and carefully prepared index serves to render every portion of the work immediately accessible.

We can cordially recommend this work, not only to the specialist, but to all members of the profession who are desirous of becoming familiar with a department of medicine the importance of which it is hardly possible to overestimate.

The fourth volume of this great surgical work is now before us. We are pleased to find that it worthy maintains the high standard of excellence attained by its predecessors. Of the plates which accompany this volume it is but fair to say, that those illustrating the minute structure of tumors are masterpieces in their way, reflecting high credit upon Dr. Butlin, who furnished the drawings, as well as the publishers who had them reproduced.

The authors of the various articles are all Englishmen or Americans, so that we may speak of an Anglo-American, instead of an international volume. However, the English reader will not be disposed to find fault with the editor on this account, since it is altogether pleasant to read an author, even if his subject is purely medical, in the original, than in the most perfect translation possible.

Injuries of bones are ably discussed in the first article, which is written by Dr. Packard, of Philadelphia. It is a painstaking chapter, admirably systematized, so that the subject of any special fracture can be quickly found. Dr. Burwell contributes an excellent treatise on the various diseases of the joints. Synovitis, ankylosis, the different nerves, and articular tumors, are successively considered in the clear, forcible, and practical manner so characteristic of this well-known author.

In the article which follows, the subject of excisions and resections, both from a general point of view and as regards special topographical details, is thoroughly discussed. It is from the pen of the editor, and leaves no room for adverse criticism. Exactly why Dr. Fenwick, of Montreal, is given room for a separate chapter on excision of the knee-joint is hardly apparent, since his particular method of operating is sufficiently known, and he deserves the prominence given him.

Dr. Bunke has been selected to write the article on tumors. This essay is interesting and instructive, more as regards the pathology of neoplasms, which is elaborately explained, than with reference to operative surgery. Nevertheless, as his surgical principles are sound, we are not disposed to quarrel with the author for being an excellent pathologist. We are unaccustomed with surgery where the intricate subject of new-growth is dealt with in a more satisfactory and strictly scientific manner. The late lamented Dr. Lidell is the author of a posthumous contribution on injuries of the back. It is a profound and elaborate study, the article of which fills the mind with deep sorrow that its gifted author should have died before the completion of the great work to which he rendered such efficient service.

The concluding article of the present volume is on malformations and diseases of the spine. Frederick Treves, of London, is the author of this important part of the work. It is well that he has no pet notions to foist upon the profession, but displays everywhere a just appreciation of the different forms of systematized and compound diseases. In this branch of surgery he has found a field of great usefulness for which he is well fitted to render an efficient service.

The concluding article of the present volume is on malformations and diseases of the spine. Frederick Treves, of London, is the author of this important part of the work. It is well that he has no pet notions to foist upon the profession, but displays everywhere a just appreciation of the different forms of systematized and compound diseases. In this branch of surgery he has found a field of great usefulness for which he is well fitted to render an efficient service.

This is a handy pocket-volume for the student. It contains fifty-nine illustrations, all but two which are colored as original. Some of them are only slightly modified, however, from cuts that are already familiar to the reviewer. As a whole they are well executed, and though scanty in number, are an addition to the volume. Diagrammatic illustrations are rapidly becoming popular, because the student can comprehend them. The authors of this volume seem to appreciate this fact. Some of the diagrams are happily colored.

As regards the text, accuracy and brevity are combined. All manuals of this kind can be made useful if not abused. They cannot fill the place of such works as those of Quain, Sappey, Henle, and others, but they are valuable adjuncts if used in connection with them. The few errors of statement which exist in this work will doubtless be eliminated in a subsequent edition. The type is clear and the volume is tastefully issued.
Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, January 23, 1884.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

(Continued from p. 196.)

Dr. FRANK FERGUSON presented specimens illustrating PERICARDITIS, LOBAR PNEUMONIA, AND PLEURISY, occurring in a male, twenty-five years of age, married, a native of the United States, and a sailor by occupation. He was taken sick on December 27, 1883, and on January 4, 1884, was brought in an ambulance to the House of Relief in Chambers Street. He said he used stimulants freely; although conscious, he was not able to give a clear history of his illness. On admission he was well nourished, the entire surface of the body was covered with an erythematous bluish, which disappeared on pressure. His temperature was 102° F.; his pulse 108 beats to the minute, and his respiration 44; the physical signs of bronchitis over the entire chest were present, also evidence of extensive pleurisy on the left side, and consolidation of the left lung in the axillary line. The elevation of temperature, his weak, rapid pulse, and frequent respiration continued until death. During the last four days of his illness he was delirious, the delirium, toward the last, alternating with stupor. There were no friction-sounds heard over the precordial area, but the pericardium was known to be distended with fluid. Patient died of heart failure, in a comatose condition, January 20, 1884. At autopsy the following lesions were found: The heart was normal in size; the pericardium was distended with purulent fluid and covered with a thick layer of recent fibrin. The muscular structure of the heart was normal, and its valves were competent. The left lobe of the liver was covered by recent lymph, beneath which the pulmonary tissue contained very little air; felt tough and leathery. The upper lobe was congested and oedematous. The right lung was congested and oedematous. The spleen was large, soft, and easily torn. The liver and kidneys were swollen and granular; the brain was congested.

Dr. Ferguson also presented specimens illustrating CYSTITIS—PYELITIS—CHRONIC DIFFUSE NEPHRITIS—OLD INJURIES OF THE RIGHT LEG, occurring in a male, fifty-nine years of age, a native of Belgium, and a teacher by profession. Twenty years ago he sustained injuries to his right knee and ankle, the nature of which he was unable to describe, nor was he able to give any idea of his treatment at that time. He said he fell, and was at the time in Paris. He was received and treated in the House of Relief, since the 5th of the present month, for contusions of the lower part of the abdomen and scrotum, and laceration of the urethra in the perineum. These injuries he received while profoundly intoxicated, and he did not realize his condition until the next day. Several incisions were made in the scrotum, and the operation of perineal section was performed at a point opposite the rupture in the urethra. The following day he had a slight chill, and his temperature was at 100° F., and his pulse 100. While all the incisions made in the scrotum and perineum did apparently well, he gradually failed, became delirious, and died two weeks after the operation.

On post-mortem examination there were extensive hemorrhages into the lower third abdominal recti muscles, into the tissues of the scrotum and of the perineum. The bladder was hypertrophied, and its mucous membranes were inflamed. The left renal artery were very small; the pelvis of the left kidney was much dilated and congested. The kidney was almost completely atrophied. The right kidney was very large, its pelvis was dilated, its ureter was large; the mucous membrane of both the ureter and pelvis of the kidney was markedly congested. There were numerous small abscesses in the cortex of the right kidney, and the organ presented the lesion of chronic diffuse nephritis. The heart was markedly hypertrophied, its valves were competent, and there were patches of atheroma in the anterior segment of the mitral valve and ascending portion of the arch of the aorta.

The lungs were congested and oedematous. There was considerable atrophy of the convolutions of the brain. The liver contained slight excess of fibrous tissue and fat, the fat deposited at the periphery of the lobules. The peripheral vessels were atheromatous, and the vessels of the kidneys presented the lesion of endarteritis obliterans.

DILATATION OF THE STOMACH.

Dr. J. C. Peters presented a dilated stomach, removed from the body of a patient whose clinical history he related at the stated meeting held December 26, 1883 (see Medical Record, vol. xxv., p. 77). The stomach was dilated to four or five times its normal size, and Dr. Peters remarked that, during life, no apparent effect was produced by medicines administered by the mouth. The immediate cause of death seemed to be pneumonia. The autopsy and microscopic examination was made by Dr. Ferguson, who furnished the following report:

The stomach is very much dilated, its muscular walls hypertrophied, and its mucous membrane is partially digested. There is a stricture at the pylorus which admits a cylinder a quarter of an inch in diameter. The tissues around the pyloric orifice are much thickened. There is an area of thickening in the wall of the duodenum, just below the pylorus, lenticular in shape and about one inch in diameter and one-half an inch in thickness, composed of smooth muscle and fibrous tissue. The tissues surrounding the pylorus are largely fibrous, but in some places narrow bands of smooth muscles are seen. The pneumonia is of the croupous variety. The nodules seen in the organs were military tubercles, but of these there were only a few, and on the surface of the liver and kidneys; none were found in the interior of the organs.

CARCINOMA OF THE PYLORIC EXTREMITY OF THE STOMACH.

Dr. Beverley Robinson presented a specimen, accompanied by the following history, furnished by Dr. William H. Sherman, junior assistant physician at St. Luke's Hospital:

William H. A., twenty-nine years of age, single, a native of the United States, and a gas-pipe fitter by trade, was admitted January 7, 1884. He gave no history of hereditary disease. The patient began to suffer two years ago with distress after eating, and some pain in the abdomen and chest. For the last year his condition had moved only when medicines were given, and vomiting also had been frequent and persistent. He was jaundiced for a time one year ago; had never vomited blood. On admission the patient complained of continuous vomiting and obstinate constipation. He had pain in the epigastric region and beneath the sternum, which was relieved by vomiting. He was much emaciated. A tumor was felt in the epigastric region, about two inches in width. It was movable, and changed its location from time to time, but always remaining in the epigastric region. The liver seemed to be somewhat enlarged. While in the hospital only a small quantity of milk was allowed by the mouth, the patient being nourished by the rectum. Stimulants and anti-emetics were administered.

The patient's strength failed rapidly. The vomiting continued, the matter vomited being a brownish fluid,
exceeding in quantity that of the liquid taken by the mouth. The fluid vomited apparently contained blood (crystals of haemoglobin were found on microscopic examination). The tumor was still perceptible on January 12th. Death occurred on January 17th.

Post-mortem examination.—The stomach in the median line extended down to the umbilicus. The transverse colon was situated about two inches below the umbilicus. The mucous membrane and muscular coat of the stomach were moderately thickened, and the mucous membrane was congested. A stomach was enormously dilated, measuring from the cardiac end to the pylorus about nine and a half inches. The pylorus was situated under the liver in the axillary line, at a point corresponding to the tenth intercostal space. There was a growth occupying the wall of the stomach at the pylorus, half an inch in thickness and one inch in length, occupying this portion of wall symmetrically. Through the pylorus a No. 15 (French) sound passed, tightly grasped by the new growth.

The microscopical examination resulted as follows:

Carcinoma of the pylorus.—This firm ring is microscopically composed of a fibrous stroma, limiting alveoli of various sizes, some of which are filled with small cuboidal cells, other similar cells, and similar tubes embedded in the stroma. The stroma is abundant, and in sections narrow bundles and isolated cells of smooth muscle are seen in places.

Remarks.—One of the interesting points in this case is the fact that, prior to the patient’s entrance into St. Luke’s, it is stated that the epigastric tumor could not be discovered. For this reason a distinguished surgeon of our city had declined to open the abdominal cavity and resect the stomach, although it was presumable that carcinoma of the pyloric orifice existed.

At the autopsy it was remarked that the pylorus was hidden under the liver in such manner that it could not be felt by external palpation. It was doubled, therefore, by the peritoneum, but this was, it is presumed, a distinguised surgeon of our city had declined to open the abdominal cavity and resect the stomach, although it was presumable that carcinoma of the pyloric orifice existed.

The conclusion of this is, that in suspected carcinoma of the stomach repeated physical examinations at short intervals should be made before we are prepared to affirm that no tumor really is present.

As there is no ulceration of the mucous membrane at the pylorus, it is not unusual that hemorrhage during life did not occur. The man’s age is not advanced for the existence of a carcinomatous growth.

Dr. John A. Wyeoth presented a specimen of osteo-lipoma, removed from the radius of a woman fifty years of age. The growth involved the radius one inch from the carpal articulation, and the interesting feature was that it seemed to be an exostosis from the apex of which two small nodules of lipoma sprang. He regarded the combination of osteoma and lipoma as a rare occurrence.

The President suggested that the combination was accidental.

Dr. Wyeoth thought that probably it was so.

Dr. Peabody regarded the explanation by accidental relation as undoubtedly the correct one.

The Society then went into executive session.

Past and Present.-Vivisection.—M. Pasteur’s words upon this subject are: “Never should I have the courage to kill a bird for sport, but when it comes to experiments I have never been troubled by the slightest scruple. Science in that case has the right of pleading the sovereignty of the purpose.”

THE PRACTITIONERS’ SOCIETY OF NEW YORK.

Stated Meeting, January 5, 1884.

Dr. Beverley Robinson, President, pro temp., in the Chair.

Dr. Henry F. Walker read the paper of the evening, entitled,

CERTAIN MATTERS OF TREATMENT WHICH SHOULD BE LONG TO THE LYING-IN ROOM.

[The paper is published in full on p. 201 of The Record.]

The paper being open for discussion, Dr. Wm. T. Lusk said that he could agree with Dr. Walker as regards the importance of the first two points that had been made, viz., the immediate care of the perineum and the use of pessaries in convalescence. As regards the last, he was in doubt. He had had his attention drawn to the subject recently. Two infants soon after birth had suffered greatly from frequent urination. This was an unusual thing. Upon examination he found that the nurses, in the discharge of their supposed duty, had been pulling back the foreskin over the glans, and thus produced much irritation. Preputial rest being enjoined, the urinary trouble ceased.

Dr. James B. Hunter said that he had not used pessaries during convalescence.

The plan, however, commended itself to his judgment. In sewing up the perineum he used silk or catgut, instead of silver-wire. As regards circumcision, the speaker referred to his experience in a case where a Jew performed the operation; it being his sole business; he had operated more than twenty thousand times. He said that he usually found preputial adhesions in infants, but that they were not generally very strong.

Dr. A. B. Ball said that according to Dr. Walker four-fifths of infants needed some surgical procedure, which seemed to be too large a proportion. He approved of circumcision, but thought that the majority of boys grew up all right.

Dr. Walker had not looked at it quite in that way, but he knew that very many children did require some operation on the foreskin.

Dr. Bull said that it ought to be borne in mind that the operation is not entirely devoid of danger. He saw last winter a child who died from septicaemia as the result of the operation. He believed that Dr. Sands had a similar result in the case of one of the students of the College of Physicians and Surgeons.

Dr. Lusk had followed a great many of these cases from infancy on and had found, as a rule, that the adhesions entirely disappeared.

Dr. Cleveland discussed the propriety of slitting the under side of the prepuce, a little to one side of the frenum, instead of slitting the upper side, as is usual. He knew of one physician in very large practice who always operated in this way, and with very good result. Dr. Cleveland thoroughly believed in the operation and he thought that Dr. Walker was only a little in advance of the times. While visiting physician to Charity Hospital in the venereal service, he had a number of Jews under treatment, but he never had seen any of them with chancres or chancreoids. He believed that circumcision would eventually be adopted as a sanitary measure.

Dr. F. P. Kinney had had an experience very much like Dr. Walker’s. That is, he had found preputial adhesions in most cases. But he had also observed that in many cases these disappeared later on. He had also found that in many instances the adhesions could be broken up with a probe.
Dr. Bangs said that the agglutination of the prepuce to the glans was a normal condition in the newly-born. In the class of cases these adhesions can be easily separated; in the other some operation, either slitting or circumcision, is required. He had no doubt that many children suffered from lack of attention to the foreskin. On the other hand, the speaker instanced cases showing how the organ may be injured by careless operations. As to the Jews, Dr. Bangs thought that they were freer from chancroidal disease than other races, but not from gonorrhoea or syphilis.

Dr. A. A. Smith said that in the first years of his practice he had been in the habit of following the plan recommended by Dr. Walker, and had circumcised infants freely. Of late, however, he had nearly abandoned the practice; and found that by making occasional examinations of the penis, breaking adhesions if necessary, the patients got along just as well.

Dr. C. L. Dana showed a new form of portable faradic battery.

It consisted essentially of a small portable faradic coil with an arrangement, which was run by a portable Bergmann & Hart battery. [A full description will be given, with illustration, in a future issue of The Record.]

Dr. Beverley Robinson showed an instrument for tapping the pericardium, the main feature of which was a device by which, without admitting air, the trocar could be withdrawn and a blunt canula inserted in its place.

Correspondence.

OUR PARIS LETTER.

DIABETES MELLITUS—SUICIDES IN PARIS—THE AMERICAN HOG IN PARIS—SCAVENGING THE STREETS OF PARIS.

Paris, January 30, 1884.

Professor Bouchardat has just brought out the second edition of his work on "Glycosuria, or, Diabetes Mellitus, a subject to which he has devoted his attention for nearly a century. This is a complete work on the subject of which it treats, and is the result of long experience and personal observations which he published in various periodicals, but more especially in his Annuaire de Thérapeutique, his first note having appeared in the Revue Médicale in 1836. This second edition Professor Bouchardat has added an important chapter on glycosuria, a condition characterized by an excessive flow of urine with a moderate quantity of sugar in it, which, however, persists in the blood and is accompanied by an excess of lithic acid. This latter association, according to the author, the origin of the most terrible complications that could occur in a diabetic subject has passed his fiftieth year, such as cataract, carbuncle, gangrene, softening of the brain, etc.

In studying the etiology of glycosuria, and setting aside all theory, the author determined experimentally the influence of the principal articles of diet on the elimination of sugar by the urine, which, he states, may in certain cases, exceed five hundred grammes in the twenty-four hours. He discovered that bread, the characteristic substances, and sugar were the chief elements that gave rise to the production of this extraordinary quantity of sugar in the urine. This fact contributed a good deal to a more rational system of therapeutics in the treatment of this affection, which M. Bouchardat divides into dietetic and hygienic; but he insists more particularly on the latter form, as although the restriction to a certain kind of diet (absence of glycogenic substances) is generally attended with important results, as manifested by the disappearance of sugar in the urine, this circumstance is, generally speaking, delusive, as the diminution of the amount of sugar in the urine may be only temporary and a diuretic part cannot be considered unless he can resume his former habits and live like other people, without being subject to relapses. But the form of hygienic treatment to which the learned professor attaches most importance is bodily exercise, particularly of the arms, which should be accomplished by manual work or by gymnastics, or other diuretic exercises. To this, of course, must be added temperance in all things, which should be secured by maintaining the proper functions of the skin by the use of flannel clothing, warm baths, hydrotherapy, dry rubbing, massage, etc.

In The Record of the 5th Instant you published the list of suicides that occurred in New York during the past year. It may be interesting to give the result of the official report from the statistical office attached to the Prefecture of Police in Paris by way of comparison. The report shows that in the Department of the Seine there were 542 suicides, or attempts at suicide, from January 1 to December 31, 1883. The report of the preceding year gave a total of 479, thus showing an increase of over one hundred over last year. By a singular coincidence, firearms were most frequently resorted to, for, of the total for the year, there were 217 suicides by this method, of which there were 156 for Paris, and 61 for the rest of the department. There were 148 cases by drowning, 84 by hanging, and 137 by asphyxia. The other cases were accomplished by falls from high places or witnesses of apartments, also by being caught or by poisoning. Among those who resorted to firearms there were 41 females. The report adds that it was in the year 1873 that the greatest number of suicides had been committed in the Department of the Seine, there having been 687 for that year. During the same year there were 1,421 suicides reported in London, and in 1882 there were 1,140. The report for 1883 for the latter city has not yet been published.

A propos of suicides, I may here note that Dr. Paul Moreau, of Tours, in his article in the new "Dictionary of Practical Medicine and Surgery," which is being published in Paris, entitled "Suicide," makes the following remarks: "Of all mental affections suicide is the most frequent, and constitutes the most frequent cause of crime, confession, imitation," etc., facts he had already brought to notice in his inaugural thesis in 1875, and which he comprised under the head of epidemic suicide. Dr. Moreau referred to another point not less important and melancholy, the tendency to suicide in early childhood, which is already manifested in the first years of life, the symptoms of which may be recognized, and should be taken into account independent of heredity.

After the American hog, the chifonniers are creating a great sensation in Paris. You will have seen what prevarication there has been on the part of the French Government respecting the importation of American pork, for, although it was openly demonstrated by Drs. Bouchardat and Grancher that trichinosis never existed in France, and that even if it did, it could not be imputed to American or any other pork, as the French never use this article of food without subjecting it to a thorough process of cooking, which has been proved to be sufficient to destroy the trichine, the opinion of these eminent authorities has been called into question and overruled by M. Paul Bert at the Chamber of Deputies, where he obtained the suspension of the decree permitting the importation of American pork in this country.

The decree by the Prefect of the Seine, regulating the scavenging of the streets of Paris, being prejudicial to the interests of the chifonniers or rag-pickers, without any way of improving the system so many years in vogue, demonstration meetings are held to protest against the decree, which the parties aggrieved condemn as gratuitous and uncalled for, as it has been shown that, far from being
nuisance to the public, this interesting class of laborers render signal service toward the sanitation of the city. And from being simply cancelled, it assumed one of general social interest, and now, like all questions of a public character in this country, it has degenerated into a political squabble from which the authorities find it difficult to extricate themselves. A proposition has been made at the Municipal Council of Paris, anent the chifonniers, that the decree affecting them should be simply cancelled. At a meeting of the Professors of the Paris Faculty of Medicine, last week, it was decided to present as candidates for the chair of obstetrics at the School of Medicine, Drs. Tarnier, Genuiot, and Charpentier, in the room of Professor Payot, promoted to the chair of clinical obstetrics. The general opinion is in favor of Dr. Tarnier, whose standing in the profession and his other qualities would point to him as having the best claim.

THE NON-NECESSITY OF STRICT ANTISEPTIC MEASURES IN GENERAL OBSTETRIC PRACTICE.

To the Editor of The Medical Record.

Sir: In a recent editorial in The Record reviewing the question of the \"Prevention and Treatment of Puerperal Fever,\" this question is asked: \"Shall the general practitioner everywhere religiously obey the instructions given, for instance, by Dr. T. C. Thomas in his prophylactic measures?\" In the several papers and discussions that have appeared in your pages the subject has been viewed from the standpoint of those who are obstetricians engaged in city practice, and chiefly viewing the subject from the point of view of hospital life. These gentlemen, however, have not confined their conclusions to the hospital engaged, but, as teachers, have addressed wider audiences than merely were in attendance on the meetings of the various societies where these papers were read. But every general practitioner must decide this matter for himself, guided by the lamp of his own experience, or of that of those similarly situated with himself.

For some years the opinion has gained ground that puerperal fever is due to puerperal infection, which infection is either auto-infection or infection from the contact of infected articles, etc., and is identical with the septicaemia or infection that arises among those who are suffering with surgical injuries, and consequently we would expect that it prevails in the same localities and under the same conditions as we find the surgical disease. But in healthy towns and country localities the latter disease is not common, and in some localities is rare, and we are justified in coming to the same conclusion as to the latter. Wounds of all kinds in these favored localities heal without the necessity for the strict aseptic measures required in hospitals and the viaitated atmosphere of crowded urban life; and we find the same condition of affairs in obstetrical practice. And, indeed, we think it would be adding needless anxiety to the real dangers and fears of maternity to insist that every parturient woman should undergo all the preparations, precautions, and procedures which are used in capital operations; and a harsh judgment to charge the physician not adopting such measures, \"with a laxity of caution closely bordering upon criminality.\" In a very large proportion of cases in general practice the patients could not, if they would, carry out such suggestions, for their home surroundings would not admit of it.

In a very large number of cases the attendant is not informed as to when his services will be needed, his advice is not sought until labor commences, and his attendance is limited to the time occupied by labor, and a day or so succeeding; then, if the patient is doing well, his visits cease. Certainly this is the case in country districts.

In a large majority of cases the dwellings of these patients are not commodious enough to admit of having a room especially prepared for the lying-in; among our poorer patients we are glad to have a bedroom not common to more than the parents themselves. Again, in a vast number of cases there is no nurse engaged, the means of the parties would not admit of it. Some female friend or relation serves in that capacity. In my own practice I have too often been glad to have ordinary cleanliness, as differing from the usual filth of their premises, and this is no exception to the experience of others. Such are some of the objections I have to such teachings that they require precautions which are impracticable in a very large proportion of cases.

The next question is: Are they necessary? This is to be decided by the results of practice, and I here offer my mite of experience. In a record of nearly six hundred cases of labor, covering a period of fifteen years in general practice, I find that three patients suffered from conditions which can be classed as puerperal fever or inflammation. Of these one was a case of puerperal peritonitis in a primipara—which proved fatal on the sixth day; she was forty-eight hours in labor, and was delivered with forceps. One was a case of pelvic cellulitis, which had its origin, I think, in some prior chronic inflammatory condition. One was a case of metritis, in a pluripara, after a short and easy labor. In several more there were febrile attacks occurring during the lying-in, which continued for from three to five days. I did not think these cases belonged to this class. During the same period I have seen three other cases in consultation or attendance which were attended by other physicians or midwives. One was a case of puerperal peritonitis. This patient contracted gonorrhoea from her husband a short time before her confinement; she was one of those who were delivered at home, after delivery; the third was a case of metritis, developing in the sixth day after confinement. This record, I think, confirms what Dr. Thomas says as to the rarity of septicaemia in country and village communities, i.e., that in many of these localities it is entirely unknown. We do not have the atmospheric and telluric conditions favorable to the development of the particular septic germ. In our parturient women we have the lacerations and contusions of the cervix, the same conditions at the placental site, the same injuries of the membrane of the vagina, and the same lacerations of the perineum. We oftentimes have retained portions of placenta and membranes and clots, our patients undergo in this same localities difficult and tedious labors, but we do not have the active principle which is to cause trouble in these favoring local conditions. Hence we do not find it necessary to treat our patients as if they had undergone capital operations or as if the genital canal were a punctured wound. On the contrary, we let nature and rest do the necessary work, rendering aid when aid is necessary.

But we are further told that in all cases of difficult labor, and in those in which instruments have been employed, vaginal disinfecting injections should be administered every fourth hour, and kept up for at least ten days. In these six hundred cases the forceps were used twenty-nine times, podalic version four times, cephalic version once, in one case it was necessary to incise the cervix with the bistoury on account of rigidity, and in a number of cases placenta was removed by introduction of hand into uterus. In only one of these cases was there any trouble following, i.e., in a case of forceps delivery, before mentioned, which died of puerperal peritonitis. To show how cases recover without unfavorable symptoms, I relate the following case: A multipara with the wife in labor during afternoon; it proved to be a case of twins. The first child was delivered without difficulty; the second was a shoulder presentation with protrusion of arm and prolapse of cord. Violent pains wedged the body deep
in the pelvis. The services of a physician, eleven miles distant, were sought, but he did not reach the house till 2 A.M.; last night’s assistance, and I was summoned, reaching patient about 11 A.M. of next day. The child being dead, I amputated arm at shoulder, and then turned child and delivered by feet. Perfect uterine contraction was secured and kept up by repeated doses of ergot, rest by morphia, and full doses of whiskey and quinine given during next twenty-four hours. Vaginal disinfecting injections were advised, but no syringe was at hand. It was not necessary for the physician to see her but once, and she made a rapid and complete recovery. Owning to the distance it was impossible to give closer attention. Sometimes we are called upon to deliver placentas, in cases where the midwife is unable to deliver it, many hours after birth of the child, and as yet I have seen no bad results, nor were any steps taken to prevent them, except occasionally to order a daily vaginal injection of warm water, and indeed this advice is not always followed. During the past three years the use of carbonized vaginal injections have been ordered where the circumstances would admit of it, and the labor been protracted and difficult. In two of these cases, notwithstanding these measures, the placentas have been disapproved. To twenty-four to thirty-six hours, one on the fourth the other on the nineth day. There was no local cause for it. Again, it is recommended that the practitioner shall take care “that all clothing be free from exposure to the effluvia of septic infection, such as typhus, erysipelas, scarlet fever, septicemia, and if he has been exposed, should change his clothes and bathe with a solution of boracic acid.” While agreeing in the main with all this, still the experience of most general practitioners in country practice proves that it is unnecessary. The thorough airing of the clothing by exposure to the fresh air while riding from house to house, the frequent bathing of the hands and cleaning of the nails, as above, there is an immunity to all that is needed. It is all that the writer has found necessary during these years of practice, when scarlet fever was prevailing as an epidemic, while attending cases of erysipelas, diptheria, and cases of injury where there was much suppuration.

From the experiences related above we feel justified in drawing the following conclusions: That the attendant should see that his hands and instruments are thoroughly clean, for which purpose plenty of soap and water, and free use of the nail-brush will suffice, except when he has been handling objects from which it would be expected that infection should arise; then the use of disinfectants becomes necessary. The most effective for this purpose is a solution of nitric acid, which ought not to be hastened by rupture of the membrane until the os uteri is fully dilatable; and the second stage be not unduly protracted, but shortened by the judicious use of the forceps—the placental membranes and clots fully expelled by securing perfect uterine contraction by manipulation and ergot, and then rest from annoying after pains by full doses of morphia.

There should be complete rest during the lying-in, so as to secure perfect uterine involution, and the healing of all the slighter lacerations and contusions which may have occurred.

In cases where more extensive lacerations of the cervix and perineum have taken place, proper operative procedures should be instituted at the proper time. The nurses and attendants should be taught the necessity of cleanliness, and the securing of that as far as circumstances will admit. By following such a course it will not be necessary for the general practitioner to treat his puuerperal patients as if they were about to undergo, or had undergone, some serious capital operation, or had had themselves emasculated into a "magical labor wound." It is not necessary nor to deliver them under the antiseptic spray, as I have seen credited to Fancourt Barnes, nor again to close up the vulva with antiseptic dressing to prevent the sucking in of septic germs, nor to inject the vagina repeatedly to prevent auto-infection, and use iodoloo, etc., to hasten the healing process; but to treat labor and the condition following as a physiological process, where nature, with favorable conditions of cleanliness, rest, and time, is equal to her work.

W. H. SHARP, M.D.

"THE ADVISE GRATIS SYSTEM."

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Dr. J. West Roosevelt has discussed this question in The Medical Record for February 2d, in a very able manner, considering the subject from many points of view, and yet has not been able to deduce any practical solution for the remedying of the admitted defects of the system. Will Dr. Roosevelt pardon me if I suggest that his inability may possibly be due to the fact that he is living in a "glass house," and, of course, cannot with ordinary consistency "throw stones"? I have no doubt but that the main remedy that I have to offer for the bettering of the evil state of affairs so forcibly appreciated by Dr. Roosevelt will meet with the approval of the profession, and do not hesitate to think that I would earnestly suggest as a true physical antagonist for this paupering poison that is so freely vended in our city, is that every free hospital or out-door patient, should earn his or her professional treatment and medical supplies by a self-surrender of themselves as illustrative subjects for purposes of clinical instruction. It should be made known to every patient who seeks medical or surgical public aid, that he can, and must if called on, thus render an equivalent, of more or less value, for the aid he receives. Every person with a particle of true pride would most willingly offer this service in return for what he receives, and those who have it not should be taught their social duties in this respect at least. The great wealth of clinical material continually lost to medical science in this city that should be utilized in the instruction of the medical students, both under- and post-graduate, who throng our schools. The very first step that I should recommend to Dr. Roosevelt, as a means of reform in this respect, is the immediate abolition of the Out-door Department of Roosevelt Hospital, or else the establishment, in connection with it and the hospital, of a clinical school of medicine. The city is overrun with a surplus of dispensaries, and the very physicians who really promote and support them for the sake of "the experience and certain prominence" they gain, are largely responsible for the bad state of affairs. Those who should apply to these dispensaries for relief are partly or quite able to help themselves. My perception of this matter has lately had a stimulus. It is my fortune to be connected with the chest class at the Bellevue Out Department, in the capacity of an humble assistant. The people who apply at this city dispensary are presumably as miserably indigent as any class in the city. Their appearance would indicate the most abject poverty. These patients receive gratis, at each visit, from one to three compounded prescriptions. It so happened that in December the cod-liver oil gave out, and the supply could not be replenished until the New Year. I explained the facts to each patient who had been receiving the oil, and urged the necessity of their taking the oil if they could afford to buy it. To my utter surprise every patient informed me that they could thus get the oil. Comment is superfluous. Now, while there are an excessive number of dispensaries that thus give aid, and at the same time help to make beggars of an immense number of people, the medical schools have great difficulty in getting together suitable classes for purposes of clinical instruction. They almost have to fight among themselves for the material. Undignified advertisements have to be placarded in the streets to draw in the people. Every out-door dispensary in the city that is not in connection
with a school for medical instruction should be closed. Every hospital in the city should have attached to it a medical school. There are many licensing powers, but there are not too many schools. Medical schools should have small classes of students, and large classes of clinical material. Such a state of affairs would mean less money for each school, but more learning in medical practitioners. It would also keep away from the dispensaries multitudes who can well afford to retain a physician. Of course I do not advocate too many medical schools. The clinical material should be kept in large classes.

There is no excuse that could be really considered valid for the maintenance of the Roosevelt Out-door Department. The New York Hospital Out-door Department is a particularly vicious institution. It deprives many a poor doctor of many a badly wanted fee, and is only of great professional value to its attendant medical staff. The city dispensaries are the most pernicious of all. They should be closed, and the money they cost the city should be equally distributed to the dispensaries in connection with the medical schools. I am informed that the managers of Demilt Dispensary have exceedingly difficult in connection with this matter, sometimes medical instruction being allowed there, but more often it is not allowed. In viewing the subject from the patients‘ point of view, it may be added with justice that they have some rights that should receive due consideration. It is too often the case that clinical instructors use the patients with absolute brutality. They are often shelved so long as to become chilled, and in many other ways are neglected and badly used. If a medical man undertakes to treat a charity patient, he should give him honest and thorough treatment; and this duty should be all the more imperative if he has used the patient for inspection purposes. It is a great satisfaction to know that many of our.inspectors are thus considerate. It was my pleasure, some weeks ago, to be present at a clinical lecture given by a distinguished clinical teacher. I was particularly impressed with the delicacy and consideration with which the patients were treated. There was privacy in unclothing them. There was a high stool for the weakly patient to sit on. There was a shawl to cover him in the intervals of instruction, and the room was kept so warm that there was no danger of his catching cold, though it was uncomfortably warm for the other occupants of the room. Here, then, is one step at least that, though difficult of putting into practice, may be made in the means of fitting the undeserving from among the applicants. Let the patient pay all the outside doctor in cash, or the clinical instructor, and in this way society at large, in a service costing time and a reasonable amount of discomfort. Furthermore, a slight charge, proportional to the ability of the patient, should be made for medicines. Even a few cents paid by a patient will preserve self-respect, and very few of the dispensary patients are absolutely penniless. The unlimited dispensing of free medicines at the city dispensaries interferes very greatly with the carrying out of this policy in institutions where it is nominally adopted. Every dispensary should have a conspicuously located contribution box, and every patient should be emphatically made to feel, by all justifiable means, that a reasonable contribution in proportion to ability would be expected at each visit. A very slight deprivation of beer, tobacco, etc., would furnish the vast majority of the poorest patients with the necessary small coin to drop in the box.

AN INFANT THAT SECREtes MILk.—Dr. Lesniewich reports, in the Paris Médical, the case of a male infant, aged ten months, that secretes milk in considerable amount. The infant has, for its size, well developed mammary glands.

## Army and Navy News.

### Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from February 10, 1884, to February 16, 1884.

PERIN, GLOVER, Lieutenant-Colonel and Surgeon, Medical Director, is granted one month’s leave of absence, with permission to apply at Division Headquarters, Missouri, for an extension of one month. S. O. 16, Department of Dakota, February 9, 1884.

WILSON, GEORGE F., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Walla Walla, W. T. S. O. 14, Department of the Columbia, February 5, 1884.

### Official List of Changes in the Medical Corps of the Navy, for the week ending February 16, 1884.

COURS, S. F., Medical Director, to the Naval Medical Examining Board, Philadelphia, March 3d, as the relief of Medical Director P. J. Horwitz, who retires on that date.

## Medical Items.

### Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending Wednesday, February 16, 1884:

#### Hot Water Injections to Arrest Uterine Hemorrhage.—Dr. Frederic S. Sellev, writing concerning an article on the above subject in a recent number of The Medical Record, says: “At that time I was treating a very obstinate case of menorrhagia, and failing to arrest the hemorrhage by the usual means, I resorted to the use of the injections of hot water per rectum, with very gratifying results. Mrs. C——, aged forty-eight, married, two children. She began to menstruate at the age of twelve, and since that time the menstrual periods have been irregular and frequent; the intervals varying from two to three weeks. The loss of blood at each menstrual epoch has been large and continuing for several days. During the last two years the intervals have been growing longer, varying from two to five months. Last March (1883), after an interval of three months, I was called; found her bleeding freely, very weak and restless. She informed me that she had been unwell for ten days, the hemorrhage increasing from day to day. A careful
examination gave no evidence of the existence of vegetations within the uterine cavity. I began the usual course of treatment—ergot, astrigents, vaginal douche, etc.—with very unsatisfactory results, the improvement following the use of any of these remedies being only temporary. The only remedy which seemed to exert any permanent influence was opium, and under its use there was a gradual improvement, until the hemorrhage finally stopped altogether and did not return again until the following September, six months later, and again in December. At these times the loss of blood was slight. In January, 1884, I was again called; found her bleeding profusely. She had been unwell for a week, growing worse from day to day. As before, the usual remedies made no impression upon the flow of blood. I then directed that a large bandage be put on her abdomen and renewed as often as possible. The bleeding stopped at once and did not return until the following day, when after a sudden fright it recommenced. The enema was again given and repeated in about twenty minutes, after which the bleeding stopped and has not returned."

The Prognosis in Cases of Post-mortem Wounds.—Dr. W. Thornton Parker, of Morristown, N. J., writes: "The medical journals of this country and Europe have reported during the past year several deaths in connection with post-mortem examinations. Some of these deaths have occurred very soon after the receipt of the injury, others have weakened the system of the victim for years, until some ordinary disease has found him in a state to be easily overcome. I have in mind at present two or three medical men who are suffering constitutionally from post-mortem wounds received several years ago. In looking up the matter in our text-books on surgery, I find too little of information concerning this subject. I suppose that it was generally admitted that the post-mortem wound was injurious to health to such an extent that the virus having once sharply attacked the system, it would be well-nigh impossible to eradicate it. I am well aware that many post-mortem wounds are received, and that little, if any, disturbance seems to have been created by them; but I hold that the system can be, and undoubtedly often is, seriously impaired for life, the natural forces weakened, and the nervous system affected. Hamilton gives this matter very careful consideration, but omits the prognosis in such cases, and so do most of the writers to whom I have referred. In the need of a term I propose to recognize as probably the most dangerous implement inflicting this dreadful wound. My object in sending you this communication is to ask for information from the medical profession on this subject, especially concerning prognosis. During the past week, in conversation with a medical man of high standing, and a man well read in surgery, he informed me that after fifteen years he considered the poison to be so thoroughly eliminated from the system of any one receiving such a wound as to be practically non-existent; and, furthermore, he held that our bodies change so rapidly and continuously that little of the body of fifteen years ago remains to-day. Early in 1882 this matter received considerable attention in the "British Medical Journal," and in the "New York Medical Journal," and in the "British Medical Journal," and in the case, at least, was reported where the post-mortem wounds had persisted for fifteen years! (See British Medical Journal, February 10, 1883.) If the warts can persist that long of time, the poison can continue its injurious effects as long, and even longer, in my opinion, and as I have reason to suppose, in the opinion of most medical men, and I think the practical surgeons. I see the importance of this subject, and for reference to works or papers which sustain either view of the prognosis mentioned."

The Climate of Newport.—At a regular meeting of the Newport Medical Society, held February 5th, at which twelve members were present, it was resolved: That the Newport Medical Society endorses the opinion advanced by Dr. H. R. Storer, that the winter climate of Newport is preferable to that of the rest of New England for certain forms of pulmonary diseases, and for general invalids, provided that when here the patients are under proper hygienic conditions as regards location, etc.

Sculptor's Clay for Electrodes is recommended by G. Apostoli in the Bulletin Général de Thérapeutique.

Morphine against Sea-sickness.—In a letter to the Bulletin Général de Thérapeutique, Dr. Pietra Santa calls attention to the value of morphine in sea-sickness, as recommended in 1881 by Baron de Thérsèpolis. It is given hypodermically, and followed by a purgative. A few injections, sometimes one, will suffice.

Scenes in Pasteur's Laboratory.—The following somewhat gruesome description of M. Pasteur's laboratory, is taken from a recently published volume entitled, "L'Histoire d'un Savant par un Ignorant": "All the animals in the laboratory, from the little white mice hiding under a bundle of cotton wool to the dogs barking furiously from behind their iron-railled kennels, are doomed to death. These inhabitants of the laboratory, which are marched out day after day in order to be subjected to operations or other experiments, share the space with still more gashly objects. From all parts of France hampers arrive containing fowls which have died of cholera or some other disease. Each has been put in a basket bound with straw; it contains the body of a pig which has died of fever. A fragment of lung, forwarded in a tin box, is from a cow dying of pneumonia. Other goods are still more precious. Since M. Pasteur, two years ago, went to Pauliac to await the arrival of a boat which brought yellow fever patients, he receives now and then from Le Foucault a bot of "sourcements." Tubes filled with blood are lying about, and small plates containing drops of blood may be seen everywhere on the work-tables. In special stores bottle-like bladders are ranged resembling small liquor bottles. The prick of a pin into one of these bladders would bring death to any man. Inclosed in glass prisons millions and millions of microbes live and multiply."

Combination of Skin and Sponge-grafting.—Dr. Fred. B. Robinson, of Grand Rapids, Wis., sends us the following instructive history: "M. B., a healthy girl, aged six years, became severely burned on the nates, vulva, and both thighs. In all about one hundred and eighty square inches of skin were burned off. The shock was very severe. The urinary secretion was suppressed for two days, but was finally restored. Excudation from the raw surface was great; the pulse was feeble. In two days it required three times a day for some time. Flour, oils, etc., were employed to exclude the atmosphere from the raw surface, but under all medications the child swarmed from extensive suppuration. It became a question of active treatment or death. A combination of skin- and sponge-grafting was resorted to. Pasteboard boxes were applied so as to keep all material, cloths, etc., from the burned parts, as all bandages caused excessive suppuration by irritation. The burned surfaces were made bare and free as possible. Fine sponges were soaked in alcohol and carbolic acid (100 to 20 parts) for thirty-six hours. Thin layers were cut from the outside of the sponge, and these were applied on the burned surface. The edges of the thicker parts best adapted is about that of blotting-paper, so that the granulations can grow up in the meshes of the sponge, absorbing it as they grow. The sponge- and skin-grafting was done from the edge of the denuded surface. Every three weeks I peeled some forty skin-grafts from my arm or leg, and saddled them with the surface of the four layers of prepared sponges. After this application suppuration would be partially suppressed, followed by a rise of temperature for a few subsequent days. Whenever the child lost weight the healing was stationary. Under this method healing was marvellous. The granu-
lations would spring up between the meshes of the sponges, and the skin-grafs furnished new base-points of skin growth. Newly formed skin would soon extend beyond the application, leaving some of the thicker nodules of the sponges unabsorbed. No bandages were placed on the sponges, as the parts were at rest and fairly quiet. The subcutis of the bisumth was sprinkled on the burned surface, which very much diminished suppuration and odor, and kindly promoted healing. The wounds are almost healed at writing. I think such combination will be found a useful method in healing extensively skindened surfaces and ulcers.”

A REMARKABLE DWARF.—Dr. A. Ten Eyck sends us an account of a dwarf living near his residence, in De Freeville, N. Y. It would very much interest Barnum. The person in question is a young lady, aged eighteen years, who measures only twenty-seven inches in height. She is well proportioned except the head, which is rather large, has lost her teeth, and has never menstruated. Her intelligence is small, she cannot speak. She can stand, but cannot walk. Her general health is good.

MORTALITY STATISTICS FOR 1883.—Small-pox.—In 1883 there were only 12 deaths, against 260 in 1882. This shows good work in vaccination and disinfection by physicians and the Board of Health. The usual mortalities were smallpox, the confluent cases; eight per cent. of the semi-confluent; and four per cent. of the distinct, or discrete forms.

Measles.—In 1883 there were 716 deaths, against 913 in 1882. This also shows reasonably good work in disinfection by physicians and the authorities. Under favorable circumstances the mortality from measles does not reach one per cent.; and it is safe to say that some physicians in long and good general practice have never seen a death from it. In hospitals, asylums, barracks, and overcrowded tenement-houses it is often a very serious disease. Cachectic, scrofulous, anemic, and badly fed and clothed children are the principal victims. In these the mortality may vary from four to fifty per cent.

Scarlet fever.—There were only 743 deaths in 1883, against 3,066 in 1882. This again shows good sanitary work on the part of physicians and inspectors, aided perhaps by favorable weather and general cleanliness of the city. Still, scarlet fever is apt to prevail for several years and then almost die down, perhaps for want of susceptible from some peculiarity in the weather. Mild winters, when better ventilation can be secured, possibly stop its progress. Although contagion is the prime cause, weather has some influence on its spread. Of 56,000 deaths in London, in twenty-four years, eighteen per cent. were in the spring; twenty-three per cent. in the summer, thirty-five per cent. in the fall, and twenty-four per cent. in the winter. November is often the most fatal month, unless the weather is mild: of 3,000 deaths, 400 took place in November, 330 in December, 200 in January, 140 in February, 157 in March, 167 in April, 177 in May, 213 in June, 282 in July, 257 in August, 327 in October. Hence contagion prevails at all times, and most in the fall of the year. The difference between the fall and spring months is as great as thirty-five per cent. in the former and as low as eighteen per cent. in the latter.

Diphtheria.—There were only 909 deaths in 1883, against 1,525 in 1882. The mortality varies from 1 in 10 to 1 in 3. Of 80 fatal cases, 60 will arise from laryngeal troubles, and 20 from exhaustion. Although it may prevail in all places, it is most common in low, damp, swampy, and marshy towns, or parts of towns with bad drainage and where foul exhalations are most common. The influence of contagion is well established, and the lower mortality last year may be attributed in part to sanitary improvements and disinfection.

Membranous croup.—There were 640 deaths in 1883, against 1,702 in 1882. The majority of them were undoubtedly from diphtheria.

Erysipelas.—There was a slight increase, from 149 deaths in 1882 to 173 in 1883. The mortality in ordinary and surgical cases is from three to seven per cent.; in very young children (infants) fifty per cent. or more. It is most common in hospitals in the spring months.

Whooping-cough.—There were only 327 deaths in 1883 against 668 in 1882. This either shows that disinfection is better carried out, or a diminution of the epidemic tendency.

Typhus fever.—There were only 15 deaths in 1883 against 65 in 1882. This disease always arises from the overcrowding of filthy people. It is generally imported and is very contagious. Only 388,547 emigrants arrived in 1883, against 455,456 in 1882, so that the danger from ship typhus was less; still the figures show good quarantine service, or else that the short passages of the steamships do not allow time for its generation; and doubtless more watchfulness over crowded lodging and tramp houses and speedier stamping out of the contagion by the health authorities.

Typhoid fever.—There were 470 deaths in 1883, against 362 in 1882; as this disease generally arises from infection and obstructed house-drainage the increase shows that these causes are in operation in country health resorts, etc., as, singularly enough, comparatively few cases arise in the city. Sewer-gas and large sewers do not cause it; but infection and small, obstructed, and badly ventilated drains.

Cerebro-spinal fever.—There has been a great increase in this disease from 238 deaths in 1882 to no less than 522 in 1883. It is probably also one of the filthy diseases which is most common in cold and wet weather, and it has been suggested by Dr. J. C. Peters that it is a foul-air rheumatic fever.

Periperal fever have not increased or lessened; there were 407 deaths in 1882, and 406 in 1883. If they arise from infection, erysipelas, or foul air, the measures of disinfection do not seem to have been as efficient as in some other diseases. Perhaps when carbolic acid, or rather alcohol, has been abandoned for corrosive sublimate and the acids the results may be better.

Malarial diseases have lessened from 540 deaths in 1882 to 227 in 1883. The lessened supply of water may have let wet places dry out, and malaria with it; but perhaps the treatment of these diseases is now better than it was even one year ago. So note it be.

THE ETIOLOGY OF PHthisis is expressed by a professor in Westminster Hospital College as follows (Students' Medical Journal): Some are born to phthisis, Some acquire phthisis, and some have Phthisis thrust upon them.

A CASE OF SPONTANEOUS COW-POX is said to have occurred in the Department of the Gironde, France. The lymph has been collected and inoculated.

STRYCHNINE AND ALCOHOL.—M. Dujardin Beaumetz contends, in the Bulletin de Thérapeutique, that strychnine has some antidotal power against alcohol, and that more alcohol can be given to animals without causing death, if strychnine be at the same time administered. It is useful also to combat the acute effects of alcohol, such as drunkenness and delirium tremens; but it does not at all prevent the degenerating action of this substance upon the tissues.

OXIDE OF ZINC AS A SUBSTITUTE FOR IODOFORM.—In the treatment of wounds, Dr. Petersen, of Kiel, considers zinc oxide a good substitute for iodoform. It is cheaper, and is not poisonous.

TRANSACTIONS OF THE MEDICAL SOCIETY OF VIRGINIA, Fourteenth Session, 1883.—This is a well-printed volume of 220 pages, and contains a great deal of instructive matter. The reports on advances in medicine are for the most part well done, and form an excellent feature of the book.
ON THE
METHODS OF STUDYING THE BRAIN.

ABSTRACT OF THE CARTWRIGHT LECTURES, DELIVERED BEFORE THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, FEBRUARY 2, 4, AND 6, 1884.

BY BURT G. WILDER, M.D.,
PROFESSOR OF PHYSIOLOGY, COMPARATIVE ANATOMY, AND ZOOLOGY IN CORNELL UNIVERSITY, AND OF PHYSIOLOGY IN THE MEDICAL SCHOOL OF MAINE.

LECTURE II.

METHODS OF MANIPULATION: REMOVING, PRESERVING, AND EXAMINING THE BRAIN.

(Concluded from page 199.)

The method last described (continuous arterial alinjection) brings the preservative liquid most abundantly to the parts covered by the vascular pia, and is thus best adapted for the study of the eotal features of the brain, the base, the arrangement of the fissures and gyri, and the contour and proportions of the organ. With frontal brains, where the parieties are thin and the ento-occipital plexuses very large, this method may suffice for the due preservation of the entire mass; but with the adult human brain, if the special object be the determination of the form, extent, and connections of the cavities and the contour of their walls, arterial alinjection should be replaced by or combined with the continuous injection of alcohol into the celleda themselves.

The advantages of the repeated injection of alcohol into the celleda are as follows: 1, it facilitates the preservation of the general peculiarities of the preservation of the immediate celledarian parietes, and their contour is thus retained; 2, the apposed surfaces are kept apart, so that there need be no doubt as to the celledar limits; 3, when either of the parietes is removed, the celleda appears as a distinct excavation, and not merely a slight depression; 4, in transsection, the celledarian lumen is clearly defined.

The continuity of the flow is provided for by the connection of the canula through a rubber tube with a reservoir of alcohol.

The place of injection varies according to the nature of the preparation desired. When the entire cavity is to be filled, or when the boundaries of the aula, etc., are to be studied, the canula is conveniently inserted into the orifice left by the removal of the hypophysis. The canula may even be tied into the infundibulum, but this measure is of doubtful utility. If there are reasons for not mutilating the mesial part of the base of the brain, the tip or side of a temporal lobe may be cut off and the canula inserted into the medicaorn; or a postcornu may be reached in like manner; the tubular mesocorm forms an admirable orifice for the reception of the canula, and, if the brain be transected at the mesen, either division may be alinjected separate.

During injection, the brain should be supported in such a way as to occasion the least possible pressure. When the entire brain is to be prepared by alinjection into both the arteries and the celleda, the former are washed out with warm water or normal salt solution (water, 5,000; sodium chloride, 15), or a ten per cent. solution of chloral hydrate, while it is still in the saturated brine in which it was placed after extraction. The alinjection canula is then secured in the basilar artery, and the cut ends of other arteries are tied. A towel or other piece of porous cloth is passed under the brain, and the latter thus transferred to a vessel of fifty per cent. alcohol; the ends of the towel are secured at the edge of the vessel so as to support the brain in its hollow at a proper level, the base being just above the surface of the liquid.

The flow of alcohol is regulated by "pinch-cocks," it is naturally more free through the celleda than through the vessels, and the latter can be cut off by a small suture provided for. There should be a faucet near the bottom of the vessel and another near the top, a rubber tube leading from each into a receptacle holding at least as much as the reservoir of alcohol; in the mouth of the receptacle is set a funnel with a fine cloth to exclude particles which might clog the canula or the vessels. The ordinary outflow occurs by the upper faucet, but, when some adjustment or examination is required, the lower one is opened until the parts are exposed.

A brain preserved by one or more of the methods above described not only retains its natural shape and cavities, but is so firm of texture that it may be handled freely and carried like stearin. How much more available it is that fresh brain for the macroscopic study, an permanent macroscopic preparation can hardly be realized without actual experience. Each year, in our great cities, scores of human brains fail of their greatest usefulness or are altogether lost for lack of timely and systematic preservative measures; each year, likewise, scores of young doctors are graduated without the practical knowledge of the brain which they ought to have. All over the country, too, are curators of museums, physicians, and teachers who would greatly prize a human brain for exhibition or study. The skilful and public-spirited anatomist who will supply this legitimate demand, and utilize this wasted material, will at least be entitled to the gratitude of all who may be directly or indirectly benefited by his enterprise.

The brains of cats and other small animals are more easily cared for than that of man. Ordinarily, they should be left in a part of the cranium, and the edge of this may be clamped at the end of a wire, or the whole supported in a wire cage or a cup of sheet-lead or blockings.

Amphibian brains should always retain a part of the skull, which may be securely held by means of the "garment-clasp" already mentioned. Since the delicate tissue will not resist even the weight of the canula, the latter is secured at a little distance from the brain, and the alcohol permitted to flow at the orifice.

The best results from alinjection of the amphibian brain as a whole are when the alcohol is admitted through an orifice in either hemisphere; but, if both hemispheres are to be kept uninjured, the metatala may be partly detached. Strong alcohol may be used at the outset, but the brain must be first soaked in water or "normal salt solution" for 15 to 20 minutes to prevent adherence of the pia.

SOLID INJECTIONS OF THE CELLEDA.—The advantages of a solid cast for studying the form of an irregular cavity are so great and so obvious that the rarity of such preparations is only to be explained by the prevalent neglect of all celledarian matters, which was referred to in the first
lecture. The coelie of the cat have been injected with the three following mixtures: 1. Plaster-of-Paris and gelatin, equal parts. 2. Paraffin colored with orange chrome, melting point, 45° C. 3. Base-plate "material" (white and green) (used by dentists), with a slight addition of gutta-percha and rubber in benzine, and of paraffin to lower the melting point.

All of these made good casts, the last named being the toughest, and therefore most satisfactory.

Removal of the brains of young subjects and small animals.—The saw is rarely appropriate, excepting when the entire head is to be hemisected. The instruments to be used are nippers, coarse, curved scissors, the trephine, and the dental engine. Of these, the most useful are the nippers, the "diagonal, side-cutting nippers," of the dealers in hardware.

Notwithstanding their name, the nippers are perhaps more useful for breaking than for cutting the skull in exposing the brain; all pulling upon the dura must be avoided, and the scissors may be employed for dividing the dura and thin portions of the bone. With children one or more years old, parts of the cranial bones are too thick for the nippers, and may be penetrated by the trephine. The marmoset exhibited at the lecture had its brain removed by means of a burr and small circular saw operated by the dentist. The engine was adapted for manipulations upon small animals and fetuses, especially when the brain is to be exposed while fresh, so that any pressure or traction may do harm; by it, also, the calva may be detached in two pieces, as already described for the adult, and, finally, the base of the skull may be removed piecemeal, either for ordinary exposure of the brain or in the isolation of the area of the cranial fossa.

Dissection of the brain.—From the practical standpoint, encephalic anatomy contrasts strongly with the anatomy of the rest of the body. With the latter, dissection is universal, and sections are seldom made; with the former, sections, microscopic or macroscopic, are the rule, and, if I have said almost unknown. The difference is due to the "nature of things," just as is the preponderance of osteology over neurology, but, like many other natural conditions, it may need modification.

The advantages of sections for surgical, pathological, and regional study are obvious; they are easily made, even with the fresh adult human brain, especially by methods devised by Cullen. Owing to the fact that the human brain were like that of a frog or Necturus, or even an opossum, with the several segments of approximately equal size, and nearly upon the same plane, the common method would be more appropriate for macroscopic study. But, in view of the extreme cephalic flexure and the overlapping of certain segments by others, the objections to sections are as follows: 1. They present plane surfaces which do not naturally exist in the brain. 2. They are almost invariably oblique with respect to the cordial axis. 3. They always include more than one encephalic segment, and are, therefore, so far as the beginner is concerned, apt to be more confusing than instructive. Admitting that sections have their uses, what I wish to insist at section-making be practised less, but dissection more.

The methods of dissecting the brain taught in the Anatomical Laboratory of Cornell University may be indicated briefly as follows: 1. The art of dissection is acquired upon the brains of common mammals. 2. Alcoholic brains are dissected before fresh ones. 3. The normal, macroscopic structure of the organ is carefully studied before the microscope is used or pathological specimens examined. 4. In addition to sections with large knives, dissections are made with small scalpels, and cavities are explored with blunt points and blow-pipes. 5. Delicacy of manipulation is insisted upon.

Let us examine into the soundness of these methods.

First.—Aside from facilitating the comprehension of encephalic morphology and imparting manual dexterity, the value of preliminary dissection of the brains of common mammals depends upon the correctness of the three following propositions: 1. The human brain, even under the most favorable conditions, is more or less difficult to obtain, preserve, and dissect. 2. The most real and lasting kind of knowledge is that which is obtained, not from descriptions or plates, nor even models, but from actual handling and inspection of the thing itself. 3. Notwithstanding man's obvious physical peculiarities, his reputed mental and moral distinctions, and his presumed destiny, the human brain contains few, if any, parts visible to the unaided eye which are not represented in the brain of some other mammal.

As compared, therefore, with the study of descriptions or plates of the human brain, the actual brains of cats, dogs, rabbits, monkeys, sheep, etc., may be examined in the expectation of learning the forms, connections, and relative positions of parts, and, neither last nor least, their names.

Were the human brain absolutely inaccessible for dissection, as it is for experimentation, the anatomist would be forced to follow the example of the physiologist and gain all his encephalic information from animals. In view of the inconvenience and expense of this procedure, the human brain is preserved, if well-preserved human brains, to permit their dissection by beginners is, as I said five years ago, as if journeymen carpenters and tailors were to learn their trades upon rosewood and cloth of gold. Fiat experimentum in corpore vili.

Second.—The second rule is based upon three practical considerations: 1. Of the visible features of encephalic form, relative position, and connection are distinctly morphological, while color, like histological composition, has a physiological significance. 2. The fresh brain is less easy to cut, and requires constant support, whereas the alcoholic may be held in any position and carved like cheese. 3. The beginner should advance cautiously, and therefore with and the medical student is especially liable to interruption. The fresh brain remains fresh but a very short time, while the alcoholic is in itself imperishable. Leisure means not only more careful dissection, but also the taking of notes and the making of drawings; hence all the arguments which I have advanced in favor of preliminary anatomical work is a sound judgment. Daltarno states that "examine an indefinite time at slight expense, apply to all alcoholic brains in general, and to those of cats and other animals of moderate size in particular.

After repeated dissection of alcoholic preparations, the anatomist is better qualified to manipulate the fresh brain and to appreciate its beauty.

Third.—This rule is in strict accordance with common sense, and with custom in most branches of learning. Its two divisions have been separately enunciated by writers who certainly were not ignorant whereof they spoke. Whether or not, in some cases, the authors of histological papers are not altogether clear respecting the position and relations of the parts concerned, the system is obscured, one of this number, a number of the number of readers of such contributions who neither appreciate their excellences nor recognize their defects from a lack of adequate familiarity with the gross anatomy of the brain.

The objections to the primary employment of the microscope do not apply to the use of a simple lens like the "tripod magnifier" or "liner tester," which assists the eye to see more plainly that which is already visible, but introduces neither optical nor histological complications.

Fourth.—Large knives are useful in making sections, and in reducing the brain so as to permit ready access to the region to be examined. But it is to be noted that, excepting at the mesen, the encephalic parts are never

1 Medical Record, February 15, 1879, July 31, 1880.
2 N. Y. Medical Journal, October, 1879; The Anatomical Uses of the Cat.
bound by plane surfaces, or by straight lines, so that
the natural contours are more easily and successfully ex-
posed by means of narrow-bladed scalps and probe-
pointed instruments. The so-called "Charrière" scalpel
answers the purpose generally, but sometimes, especially
with fetuses and small animals, eye knives with still nar-
rower blades are required. In the exploration of cæliae
and the determination of the relations of membranes
and pleuresys, the dissection is accomplished less by cutting
than by "poking" and "blowing," for which the syringe
- otome, or tracer, and the flexible blow-pipe, are indis-
ispensable. When once employed the first-named in-
strument upon the brain will never willingly be without
it. The length and flexibility of the blow-pipe enable
one to blow in any direction, and to hold the object at
a distance convenient for observing the effect of the
inflation. So instructive indeed is this mode of temporary
injection that one of Oliver Wendell Holmes' "Aphorisms
for Dissections" extended to read: "Let the eye
go before the hand, the mind before the eye, and
the breath before the mind."

This rule is aimed at all forms of anatomical Philistin-
ism. Hyrtl complains (p. 62) that "some people hold
the forceps like fire-tongs, and the scalpel like a cheese-
kifle. One of the most common and perversic habits of
the two above instruments is a bad one—and when he
makes no effort to reform—: that of aimlessly
pinching and poking his specimens, especially when
showing them to others.

AN IMPROVED METHOD IN THE TREATMENT
OF CERTAIN FORMS OF SKIN AFFECTION.

By P. ALBERT MORROW, M.D.,
CLINICAL LECTURER ON DERMATOLOGY, UNIVERSITY OF THE CITY OF NEW YORK; SURGEON TO CHARITY HOSPITAL.

The method of treatment indicated in the title of this paper consists essentially in the application of medicinal substances to the skin in the form of fixed, adhesive prepara-
tions. Its object is to confine the application of the
drug to the diseased surface alone, and to secure its con-
tinued action by maintaining it in prolonged contact with
the tissues by means of a practically immovable dressing.

For the attainment of this object a number of proced-
es are employed, the following are the chief:
First, by the application of a thin layer of collodion
in the form of a powder or paste, and retaining it in posi-
tion by means of a protective coating formed by a layer
of collodion or a piece of gutta-percha tissue. Second,
by an admixture of the drug with a gelatine mass, which
is painted over the surface, forming a thin adherent layer,
with the addition of glycerine to render it soft and pliable.
Third, by the application of a thin layer of collodion
or gutta-percha solution, holding the drug in liquid suspen-
sion. Fourth, by incorporating the drug with adhesive
plaster muslins, the basis of which is gutta-percha, which
are cut into convenient shape so as to admit of accurate
adjustment to the affected surface.

I have designated these several contrivances collec-
tively—since they are all designed to accomplish the
same object—as constituting a new and improved method
in the treatment of certain forms of skin affection. I
have not the pretension to suppose that in the presenta-
tion of this subject I shall offer anything of novelty to
dermatologists, who are, presumably, already familiar
with this invention upon established methods; yet to the
profession at large, I have not have kept pace with the
recent advances made in this special field, I have thought
that a brief exposition of these procedures might not
prove uninteresting.

Although their introduction dates back one to two
years, yet they may be regarded as substantially new,
since they are not described in any of the recent text-
books on skin diseases to which the general practitioner
is accustomed to refer for information concerning the
most approved plans of treatment. It is, perhaps, scarcely
necessary to mention that it is not my intention to intro-
duce, in connection with this method, only the endeavor
to present, as concisely as may be consistent with clearness,
the main features of its application, the conditions in
which it is indicated, and an appreciation of its value
based upon clinical results, derived partly from my own
experience, but largely from the experience of others.
Since these were the devices for the topical application
of drugs were brought to the notice of the profession
sufficient time has elapsed to enable us to test their efficacy
in a variety of cutaneous disorders, and I feel assured that
of those who have experimented with this class of prepara-
tions, few will deny that their introduction marks a de-
cided advance in cutaneous therapeutics.

In order to justify the claims for superiority alleged
for fixed, adhesive applications in the treatment of certain
forms of skin disease, it may be well to glance at the ap-
pliances hitherto employed for bringing drugs in contact
with the cutaneous surface. As is well known, these
consisted chiefly of powders, lotions, pastes, plasters,
and ointments.

While these preparations admirably fulfill the desired
indications in many cutaneous diseases, yet their use has
always been found to be attended with certain disadvan-
tages. For example, powders, which are usually applied
for purposes of protection, are easily rubbed off, and
when employed for drying up an exuding surface, they
frequently form crusts, which prove sources of irritation
and aggravate the condition. Lotions rapidly evaporate,
 necessitating constant renewal, otherwise they
leave the skin dry, stiff, and brittle, thus occasion-
ing much uneasiness and distress. Of pastes and plas-
ters it may be said, that the former are used chiefly as
means of applying caustics and strong stimulants, and
necessarily have a very limited application; while plasters
as formerly prepared have never become popular as a
means of applying drugs to the skin. The resins em-
ployed in the preparation of many plasters to give the
requisite consistency act as strong irritants, often inten-
sifying the inflammatory conditions present.

Ointments have been generally regarded as the most
convenient and efficient means at our command for the
applications employed on the cutaneous surface, the
rubbed off, or absorbed by the clothing, and can only be
efficiently employed by being spread upon lint or mus-
lin, and kept in position by careful bandaging—a pro-
cedure which involves tedious manipulation, and is
more or less cumbersome. As a curious illustration of
the fashions which prevail in cutaneous therapeutics, the
venerable Erasmus Wilson says: "When first I com-
menced the treatment of diseases of the skin, water
dressings had just been introduced, and they suddenly
became the surgical fashion of the day, while a general
outcry was raised against ointments, 'greasy applica-
tions,' as they were contemptuously termed." While the
use of ointments has fortunately survived this onslaught,
yet it must be admitted that they will always be open to
the objection that they are uncleanly and offend the
tastes of our fastidious patients.

Ointments, too, often aggravate the symptoms they
are intended to relieve; their irritating quality may be
due to faulty preparation, gritty particles of the active
ingredient may be present, an impure or rancid fat may
have been employed, or the ointment when properly
prepared and applied, may be a rapid decomposi-
tion of the fat, a reaction which is peculiarly favored
by contact with the highly oxidizing surface always pres-
en in inflammatory congestions.

Another objection to ointments is that they do not
have sufficient volatility or consistency, for exclusion of
the air and complete protection of the surface. In
diseases in which the lesions are circumscribed, scattered,
and separated by large interspaces of healthy skin, it is found impossible to restrict the application of oleaginous preparations to the seat of the disease. They have the inconvenient property of diffusing themselves over the surrounding healthy surface, and, when active drugs are used, causing irritation, oftentimes inflammatory reaction of considerable severity, and thus propagating the extension of the diseased process.

In thus indicating certain defects in the classic modes of applying drugs to the skin, I do not mean to detract from their real and acknowledged utility. In irritable, highly sensitive conditions, in acute generalized eruptions of an inflammatory character, they constitute our most valuable means of cure, and for which no equally efficient substitute has been found. Neither, on the other hand, do I claim that the introduction of fixed, adhesive applications is to revolutionize the external treatment of diseases of the skin. Their range of application is by no means universal, on the contrary, it is comparatively limited. In many skin diseases, the localization of the eruption, the high grade of inflammatory reaction present, and other conditions, render their employment impossible. The point I wish to emphasize is, that the older processes are by no means perfect, and that the new appliances, by securing greater precision and permanence of action, are fulfilling a long felt want; and all authorities recognize as essential and important, constitute a most valuable acquisition to the methods employed in dermatological practice.

In this connection it may be incidentally remarked that cutaneous pharmacy has not kept pace with the improvements made in the form and character of the preparations designed for internal use, and a large part of the crude drugs and nauseous mixtures formerly in vogue, modern pharmaceutical chemistry has placed at the disposal of the physician remedies which are palatable, pleasant, and efficient. While dermatologists have been actively employed in developing the virtues of new drugs, until recently comparatively little attention has been paid to improving and perfecting pharmaceutical processes by which the highest measure of their usefulness might be obtained without their counterbalancing disadvantages.

Among the many valuable drugs with which our cutaneous materia medica has been enriched within the past few years, we may mention chrysarobin, pyrogallic acid, salicylic acid, camphor, iodide, etc. These new drugs, like many of the standard agents employed in cutaneous therapeutics, possess powerful stimulating properties, and when improperly used do positive harm. Clinical experience proves that it is not only necessary to have good drugs, but to know how to use them.

It is now generally recognized that chrysarobin is the most efficient agent known to the profession for the external treatment of psoriasis, and certain chronic diseases of the skin. The inconveniences attending its use in the form of an ointment have restricted its application and, practically, led in many instances to its rejection as a useless agent. The objectionable property of staining the skin, hair, and nails, of indelibly dyeing every article of clothing with which it came in contact, but notably its irritating effect upon the surrounding healthy skin, and the frequent production of erythematous, furuncular, and erysipelatous inflammations. These decided inconveniences were the occasion of an effort on the part of dermatologists to devise means by which the superior virtues of the drug might be retained without its attendant disadvantages. This effort was so eminently successful in the case of chrysarobin, that its application has been extended to many other drugs, and has resulted in the building up of the class of preparations which form the subject of this paper.

To Dr. Fox, of this city, belongs the credit of being one of the first to originate an expedient for confining the application of chrysarobin to the affected patches. Some two years ago (Medical News, March 18, 1882), he suggested the employment of this drug in powder, or mixed with water, forming a paste which was applied upon the psoriatic patch, and retained in place by a layer of collodium spread over the surface, or by covering it with a piece of gutta-percha tissue, the edges being rendered adhesive by touching them with chloroform.

This process, which involved considerable manipulation, and required much time and patience on the part of the operator, when the patches were large and numerous, was readily substituted by another and more convenient method.

Seseman (Monatsschr. f. Praktische Dermatologie, February 1, 1883) proposed the use of chrysarobin suspended in collodion, which is painted over the surface, forming a thin adherent coating. The medicated collodions now embrace a large number of drugs, and are used in a variety of conditions which will be referred to later. They have the advantages of being always ready for use, convenient of application, perfectly cleanly, and remain fixed upon the skin for some time.

Prof. Pick, of Prague, proposed (Monatsschr. f. Prakt. Dermatol., Bd. 11, No. 2, 1883) the use of gelatine dissolved in water as a convenient vehicle for the application of chrysarobin. In fully in accordance with its preparation he gave as follows: 50 parts of pure gelatine are dissolved in 100 parts of distilled water, the active ingredient is added in any desired proportion, and thoroughly admixed by continuous stirring. This medicated gelatine may be immediately applied or turned into a convenient receptacle, where it solidifies into a cake. When required for use, portions may be melted in a shallow vessel placed in hot water. It is then applied by means of a short, stiff brush over the surface in a thin layer. A small quantity of glycerine is smeared over the gelatine coating with the hand, which prevents it from drying and cracking. This thin, flexible dressing remains fixed to the skin for a day or two, and may be peeled off, or readily removed by the use of a little hot water. In addition to its cleanliness and other advantages, it is claimed that a view of the diseased parts may be had through the transparent dressing, thus rendering the progress of the disease visible without removing the application. I have found, however, that this transparency is rather an uncertain element, depending altogether upon the individual nature and condition of the patient.

Prof. Unna, of Hamburg, proposes (Monatsschr. f. Prakt. Dermatol., vol. xi., No. 2) a modification, which in the matter of convenience may be regarded as an improvement upon Pick's plan. It consists in combining the glycerine directly with the gelatine before it is spread upon the surface. The glycerine jelly is made by boiling one part of gelatine with three or four parts of glycerine, until they form a translucent mass. When required for use, a portion of this mass is liquefied by heating, the medicinal ingredient, being finely rubbed up with water or glycerine, is then added, and the resulting compound well shaken until it becomes a tenacious fluid. He employs this gelatine jelly in the proportions, resulting in the formation of hard and soft gelatined gelatines, containing respectively five, ten, and twenty per cent. of gelatine. The author, in conjunction with Beiersdorf, has made a number of careful experiments with the view of ascertaining the exact combining proportions of various active ingredients, and gives a series of tables embodying the results.

Dr. Mitchell, of Philadelphia, manufactures a number of medicated gelatine pasters, which are put up in quite a convenient shape. The gelatine and glycerine compositions, with which a variety of drugs have been incorporated, are moulded in solid rolls, and when required for use a portion may be cut off, liquefied by heating, and applied with a brush. I have experimented with his preparations of chrysarobin, tar, pyrogallie acid, iodine, oxalate of zinc, etc., and with very satisfactory
results. The only objection I have found is that they deteriorate in keeping, and are apt to become mouldy, which defect could, no doubt, be overcome by a larger admixture of gelatine, or by a small quantity of salicylic or carbolic acid. The gelatine preparations which I now use are made for me by Hayes & Sons, druggists, of this city.

Prof. Auspiz (Medizinische Klin. Wochenschrift, Nos. 30 and 31, 1883) proposed the use of a vehicle, which he terms traumaticin, as more convenient than either colloidion or gelatine in the application of chrysarobin and certain other drugs, as pyrogallic acid, salicylic acid, etc. This consists of ten per cent. solution of refined gutta-percha in chloroform, and corresponds to the liq. gutta-percha, U. S. P. Among the advantages which he claims for traumaticin as an excipient may be mentioned the following: It forms a thinner and more delicate artificial cuticle than either gelatine or colloidion; it is more durable, adhering to the skin two or three days or longer without cracking; it is neutral and unirritating, causing neither tension nor pain; it is more elastic, its flexibility admirably adapting it as a covering for the joints, as it yields readily to the motion of the parts; it is always ready for use, and, as it hardens more slowly, it admits of a more thorough application.

Finally, may be mentioned another method for the treatment of the same malady, under the name of preparient gutta-percha. Although not absolutely new in form, yet in their combination, impermeability, adhesiveness, and other qualities, they constitute a decided improvement upon the lead and resin plasters. These preparations, introduced by Beiersdorff upon the recommendation of Professor Unna, consist of plasters spread on muslin, the basis of which is gutta-percha impregnated with different drugs in varying proportions, some emollient, others strongly stimulant. They possess decided advantages in cutaneous disorders localized in certain regions, such as the palms, soles, fingers, toes, and interdigital spaces, on parts habitually in contact, such as eczemas of the anus and genital regions, the crease of the thighs, etc. They are cut into narrow strips or other convenient shapes, so as to admit of accurate adjustment.

Having thus described the new modes of applying drugs to the skin, it remains for us to examine the verdict which clinical experience has passed upon their value. As before intimated, this class of preparations was the outcome of an attempt to obviate the ill effects of collodion employed with different drugs in varying proportions, some emollient, others strongly stimulant. They possessed decided advantages in cutaneous disorders localized in certain regions, such as the palms, soles, fingers, toes, and interdigital spaces, on parts habitually in contact, such as eczemas of the anus and genital regions, the crease of the thighs, etc. They are cut into narrow strips or other convenient shapes, so as to admit of accurate adjustment.

Having thus described the new modes of applying drugs to the skin, it remains for us to examine the verdict which clinical experience has passed upon their value. As before intimated, this class of preparations was the outcome of an attempt to obviate the ill effects of collodion employed with different drugs in varying proportions, some emollient, others strongly stimulant. In the treatment of psoriasis, all who have experimented with the drug in these new combinations agree that the results are much more brilliant and satisfactory than by any other method of treatment. Referring to its combination with collodion Dr. Fox (The Esculapian, February, 1884) says: "Now it is a comparatively simple matter to cause a speedy disappearance of the scales in nearly every case. And it is another step in advance when we have superseded theointment of chrysarobin by applications of the remedy which do not ruin the clothing and infame the healthy skin." He has found that the efficacy of chrysarobin colloidion is materially enhanced by the addition of ten per cent. of salicylic acid.

In chronic eczema of the trunk and extremities, where there is much thickening of the skin with no moist or dry scabs, Fox has applied the compound chrysarobin pigment and produced as rapid and beneficial effects as in cases of psoriasis. He has also employed this combination in lupus erythematosus, in acne of the back, and in other diseases, with good results.

Auspitz (loc. cit.) reports admirable results from the use of this traumaticin chrysarobin in the treatment of psoriasis. After from two to twelve applications, according to the extent and severity of the disease, the infiltration and scales disappear, leaving in their place white spots bordered by a red or violet-brown line.

He gives a detailed report of a number of cases in which the psoriatic process was stopped after a short series of applications made daily or every second day. He claims that the most satisfactory results are obtained by the same treatment in prurigo, in eczema marginatum, and other parasitic diseases. In prurigo the application of the chrysarobin traumaticin immediately relieved the itching and in a few cases, after from two to six applications, the nodules had disappeared.

Dr. E. Benner, in the Annales de Dermatologie et de Syphillographie, January 25, 1884, after extolling the superior efficacy of this mode of treatment in ordinary cases of psoriasis with moderate infiltration, proposes a modification of Auspitz's plan, which he employs when the patches are larger, the infiltration deeper, and the scales thicker and more abundant. After removing the scales, he vigorously rubs the patches with a small brush of hog bristles, dipped in chloroform containing fifteen per cent. of chrysarobin. The chloroform rapidly evaporates, leaving a deposit of pure chrysophanic acid. This is then covered with a coating of traumaticin by means of a flat varnish-brush. He also employs an etheral solution of pyrogallic acid, ten per cent., as a base, regarding it as admirably adapted for employment in the gutta-percha solution, constituting an instantaneous means of destroying animal parasites.

Dr. Pick (loc. cit.) reports equally favorable results in psoriasis from the use of the glycerized gelatine, medicated with ten per cent. of chrysarobin or twenty per cent. of pyrogallic acid. He has found the glycerine applications to be of especial efficacy in the treatment of chronic scaly eczema, and eczemas associated with varicose veins. In erythematous conditions due to the action of cold, glycerized gelatine containing five to ten per cent. of salicylic acid has been applied with advantage, particularly in frostbites of the ears, nose, and fingers, the layer of gelatine exerting an equal and gentle pressure upon the parts and in this way hastens the absorption of inflammatory products. He also extols the salicylated and carbolated preparations in pruritus, both idiopathic and symptomatic.

In Billroth's clinic (Med. Times and Gazette, November 10, 1883) Iodoform collodion is used in immense quantities; it is regarded as one of the most efficacious agents of the new and vigorous treatment of eczema affecting the scalp, and bruises. Iodoform and corrosive sublimate collodions are used for condylomata and syphilitic lesions.

Dr. Taylor, in the last edition of Bunstead and Taylor "On Venereal Diseases," states that he has employed the compound chrysarobin pigment with benefit in hypertrophic and vegetating papular or tuberculoid syphilides.

Dr. Thin reported before the Clinical Society of London, November 23, 1883, a number of cases of thickened, hardened epidermids occurring upon the hands and feet, which were effectually relieved by salicylic gutta-percha plasters. In some of these cases the condition had existed for years, interfering with locomotion and occasioning great discomfort. In one case the whole ball of the foot and part of the surface of the face was covered with a layer of epidermids of extreme hardness. In this hard layer there were small isolated horny formations of the nature of corns, which produced the sensation as if the patient were walking on shot or small stones. By the use of the salicylic gutta-percha plaster the hardened mass came off, leaving a delicate rose-colored epithelium. The cure was effected by Fox, and is regarded as a most fortunate instance of the value of the compound chrysarobin pigment.
THE MEDICAL RECORD. [March 1, 1884.

without exciting conjunctivitis, oedema of the face and eyelids, and other ill effects inseparable from the use of the drug. In conclusion, this paper much beyond the limits proposed, a summary of the advantages offered by fixed, adhesive applications may be given as follows: First, complete protection, and exclusion of the air from the diseased surfaces; second, fixation of the drug upon the affected parts, thus securing greater precision and permanence of action; third, maintenance of a gentle and uniform compression, this latter modifying circulatory changes and limiting exudative products; fourth, comparative cleanliness.

It may, perhaps, be considered premature to pronounce positively upon the merits of these preparations, or to decide closely their range of therapeutic application, yet a careful study of the results of their use in the hands of others, supplemented by my own experience, justifies me, I think, in formulating the following conclusions: That the introduction of fixed, adhesive applications in the treatment of certain forms of skin affection, marks a veritable advance in cutaneous therapeutics.

That they are admirably adapted for the employment of certain powerful stimulating drugs recently introduced into dermatology, as well as other standard drugs.

That they constitute the most effective mode of applying drugs in certain pathological conditions characterized by hyperemia of the derma with inflammatory overgrowth of the epithelial elements, as in psoriasis and dry, scaly eczema.

In conditions characterized by hyperplasia of the cuticle, as in cattlegrip, corns, and over-growth of thickened, hardened epidermis, etc.

In conditions of capillary congestions of a passive character, as in acne rosacea, chronic erythema, etc.

In certain neurotic conditions, not only in essentially puriginous diseases, as prurigo, but in the pruritus, sym pathetic of other affections.

Circumvented hesitations generally, as tinea circumscripta, tinea capitis, eczema marginatum, chromyphosis, syphilitic scleroses, lupus, and, possibly, epithelioma.

No. 5 EASTFORTY-FIRST STREET.

CAN THE DURATION OF THE COURSE OF TYPHOID FEVER BE LESSENED?

BY H. D. FRY, M.D.

WASHINGTOI\N, D. C.

It would be a useless waste of time were I even to enumerate the names of our most eminent medical authorities who have answered this question in the negative, and, I dare say, a great majority of medical practitioners would acquiesce in such an opinion. Doubts concerning the infallibility of this dictum first arose in my mind after the perusal of the interesting lectures1 by Dr. Thomas King Chambers.

This distinguished clinician held the opinion that the virus of typhoid fever entered the system by way of the alimentary canal. Becoming mixed with the saliva it was carried down into the stomach and there found a soil for multiplying itself in the gastric mucus.2

The gastric disorders which occur in the first stage of the disease he recognized as an evidence that the mucous membrane of the stomach was an early recipient of the poison. The occurrence of spontaneous vomiting was looked upon as an effort of conservatism, by which means the system rid itself of the disease-germs; and, acting upon the above theory, Dr. Chambers imitated Nature by the administration of emetics.

To quote his own words, he says, "At an early stage, even after the virus has begun to act upon the system, the fever may be stayed by emptying the stomach, and

---

2 In confirmation of this theory he claims that during severe epidemics those who smoke and chew tobacco, especially if they spit out the saliva, are less liable to be attacked.

---
Thus preventing the whole dose being taken up. Those who have watched my practice will have witnessed several instances of the success of this treatment, they will have seen the fever cut short and convalescence entered upon immediately, with its characteristics of painless weepiness and emaciation, gradually passing away (page 90).

And again, he says: "When we see so often the immediate avoidance of one dose of so simple a remedy, it is difficult to avoid the conclusion that its benefit is purely mechanical, and that it acts by removing from the mucous membrane of the stomach a poison only partially absorbed and still adherent to it." (Page 91).

Such is the reasoning of this fascinating writer, who then goes on in subsequent pages to illustrate the good effect which follows the emetic treatment. On page 90 is reported the case of "W. S., a robust lad, aged fifteen, who came into the hospital September, 1860, with hot skin, rigor, excessive muscular languor, pain in the back, limbs, and head, of four days' duration, gurgling in the right iliac fossa, and rose spots." Coincident with the action of an emetic there was a universal remission of all the symptoms and convalescence began. Three other cases are given on pages 128, 129, and 132, in which the same result followed the administration of emetics.

I cannot omit to express some regret at the loose nomenclature which Dr. Chambers has seen fit to adopt. Although it is true that he recognized two varieties of low continued fever prevalent in London, and called them typhus or typhoid, according to which of the two classes they belonged; still he made no distinction in treating them, and as a clinical teacher he therefore used the two terms to include all the symptoms. I think it a pity we should miss very much, too, the record of observations made with the clinical thermometer. But for this gentleman's reputation as a close observer and practical teacher these objections would demand greater attention than is otherwise the case.

The difficulty of arriving at a correct diagnosis of typhoid fever, in its first stage, is to be considered, when we attempt to reach any conclusions regarding the effects of remedies in shortening the duration of that disease. The difficulty is, not only that we may overlook the fever when present, but that other complaints, simulating the early symptoms of typhoid, may be mistaken for the true disease and treated as it.

In the latter part of the natural duration of the course of the true disease is shorter than that of typhoid fever (as it is apt to be), we might continue in error, and attribute what would be an early convalescence to the effect of eliminative treatment. If a case of continued fever stops much short of three weeks, the natural inference is that it was not typhoid. Therefore, if by an emetic, or any means you succeed in shortening the duration of the course of typhoid fever, then must come the difficult task to prove to the skeptic that the attack was really typhoid. Otherwise an affirmative answer cannot be given to the important question which forms the subject of this paper.

Conclusive evidence of the existence of typhoid, we can take the consideration the predisposition thereto furnished by the age of the patient and by the season of the year; we can consider, also, the prevalence of the disease in certain localities and families, the existence of the usual premonitory symptoms, and the characteristic temperature wave of the body heat. The clinical thermometer is, in fact, the chief aid in the diagnosis. The morning temperature is high, and with the tendency to increase of heat on each succeeding day, are strong presumptive evidence of typhoid in the absence of other causes for the fever. And finally, the point that I wish to lay particular stress upon, in this connection, is that of the subnormal temperature of convalescence, coupled with extreme languor and emaciation, which are out of proportion to the intensity of the spent disease, i.e., when its course has been shortened. Subnormal temperature, to be sure, is a feature also of the convalescence of the disease when its course has not been interfered with; but, on the other hand, the emaciation and languor are, in that case, in unison with the low duration and intensity of the fever. In other words, whereas the duration and cause of the fever may be abridged and altered, the convalescence is the same in shortened cases as in those uninterfered with. Indeed, if there is any difference, it is shown by the emaciation yielding more slowly, or even continuing to progress for a while, in those cases which have been abridged.

Such was the experience of Dr. Chambers. In speaking about one of the aborted cases of the disease, to which I have already referred (page 128), he uses these words: "He," referring to the patient, "is now emaciating, and emaciating extensively, and convalescent. . . . The emaciation," he continues, "is a phenomenon great interest; it shows how large an amount of tissue is interstitially poisoned in typhoid fever; how large an amount requires to be carried off by destructive metamorphosis during the renewal of life. In such cases as this, when the fever is cut short, it by no means follows that the emaciation should be cut short, and in point of fact it is not so. The removal of the destroyed tissue is a necessary part of the case."

Had the temperature meter been used in Dr. Chambers' cases, I do not doubt but that subnormal temperatures would have been registered during the convalescence of his patients.

In addition to information of a positive nature, we can call to our aid, for the purpose of determining the character of the fever, important negative evidence, by excluding from our consideration the symptoms of which bear a more or less close resemblance to those of typhoid fever. Certain local inflammations, more particularly I might mention catarhal affections of the mucous tracts of the respiratory and digestive organs are to be eliminated. And I can easily conceive how a latent pneumonia, in its first stage, may simulate the early symptoms of typhoid; how, acting under such an error of diagnosis, an emetic may be given, and coincidently with its action a drop of the febrile symptoms may occur; and how, if we stopped here, the belief may even be entertained that a typhoid had been abridged.

But this sudden drop of fever heat, or crisis, which often happens at the second stage of this disease, will set with one the proper diagnosis, pneumonia, and in that the physical signs of the second stage are so well marked that none but a careless diagnostician would continue longer in error.

Catarhal affections of the gastro-intestinal tract are accompanied by a set of symptoms which, by careful watching, will usually reveal their nature. However much diseases of this part may simulate typhoid fever which runs its full course, they do not resemble (what interests us more) that disease when it has been abridged. And again, the eliminative treatment herein recommended, instead of shortening would rather aggravate any gastro-intestinal affection. If, for instance, a typhilitis should be mistaken for typhoid fever, and the eliminative and purgative treatment administered, the result would be more likely to extinguish the course of the patient than that of the disease.

In point of fact, I will now consider the one disease which offers the greatest obstacles to a differential diagnosis between it and typhoid fever in their early stages. I refer to malarial or remittent fever. In the treatment of local affections, that we have a specific fever to deal with. The question comes up, Is it remittent or typhoid? Both are accompanied by nearly similar prodromic symptoms, showing the presence of a poison circulating in the blood. Chilliness, headache, languor, loss of appetite, nausea or vomiting precede, in both, the febrile development. After the disease has become established the thermom-
matter at four different times. Another stool at 4 p.m.
20th, 11.30 a.m.: temperature 102.4°; 5.30 p.m.: 103.6°.
Did not sleep well last night; tongue dry and coated with a
white fur; bad taste; thirst; anorexia; chilly sensations.
30th, 11.30 a.m.: temperature, 102.7°; 9.15 p.m.: 101.2°.
Another restless night; some headache; nausea; one
large natural stool; 31st, 10.30 a.m.: temperature, 99°;
January 2d; 24, 10.30 a.m.: temperature, 101.3°;
Sleep well; feels better; tongue moist; appetite returning;
abdomen slightly tympanic; meteorism and tenderness in the
right iliac fossa. January 1, 1880: temperature, 98°. He had no fever after this.
His tongue had almost cleaned off on the 2d. Appetite
returned, but no solid food given until the 4th. His
temperature was recorded in very different fashions:
February 2d, 10.30 a.m.: 101.5°; 5th, 101.5°; 6th, 101.7°;
7th, 97.2°; 8th, 97.4°; 9th, 97.4°. Temperature was not
taken again until the 14th, when it was normal. He
had, at the time, just returned from a short walk and felt
exhausted. This was his first attempt to leave his
room. During the two weeks succeeding the fever he
was debilitated, and had lost thirty odd pounds by his
skins.

Case II.—On November 27, 1881, while attending M.
K. H——, then convalescing from typhoid fever, I
was asked to see her brother, F. L. H——. He was
thirteen years of age, stout and well grown. Had stayed
home from school for five or six days on account of feel-
ing tired and aching in his body. Had headache.
He was very restless. His temperature at that
time was 101.8°. He was ordered to bed and quinine given
to cinchonism. The next day (November 28th) tempera-
ture was 101.2°. The calomel and ipecac powder given.
The fever ascended for the next two days, reaching,
on the latter, its highest point—103°. It then made the
characteristic line of descent, and reached normal on the
19th, when he was examined and pronounced convalescent
and normalillian. He had lost as much flesh as his sister,
whose attack ran three weeks, and was accompanied
by diarrhea, and later by dysenteric symptoms. Was
very weak, and had no disposition to leave his bed. Sat
up awhile, for the first time, December 19th, fourteen
days after the fever had left. Had a slight return of febrile
movement, and was not allowed up any more until
December 26th. January 16, 1882, he went out for the
first time and took a carriage ride.

Case III.—Mabel D——, aged five, first complained of a
headache on Saturday, December 6, 1879. Sunday she
lost her appetite, felt chilly, and toward evening be-
gan to be feverish. Monday she appeared herself with poor
things during the early part of the day, and in the
afternoon became dull. Three grains of calomel were given,
and they produced two evacuations in the night. Tuesday:
Tongue coated; appetite lost. She was given the calo-
mel and ipecac powder, which caused bilious vomiting
and two stools, Wednesday morning (the 10th) her
temperature was 101.9°. Five grains quinine ordered.
Evening temperature, 103°. On the 11th, 12th, and
13th the temperature was 102.4°, 102.8°, and 102.4°
respectively. After this date no temperature was taken,
which is explained by a foot-note in my record-book,
stating that the thermometer had been lost. On the
16th, which was the seventh day after the administration
of the calomel and ipecac, there was scarcely any fever,
and on the ninth day it had entirely left. The attack,
which developed soon after her younger sister had re-
covered from a well-marked case of typhoid fever, was
accompanied by slight diarrhea, and on the fourth day
two rose-spots appeared. Her tongue remained coated
for some days during convalescence, pulse kept weak,
and at times rapid and thready.

Case IV.—Mrs. D——, aged twenty-seven, has been
confined to the house for the past six weeks on account of
having to nurse two of her children through attacks of
enteric fever. She has given birth to five children in
rapt upon success, and the youngest is now a nurpling.
On Friday, December 19, 1879, I gave her sufficient

1 Therapeutics and Materia Medica, vol. ii, p. 779. Fourth edition. Phila-
delphia: H. C. Lees, 1874.
quine to occasion cinchonism, but without any effect in relieving her symptoms. She had been complaining for four or five days of chilly feelings and feverishness; pain in her back and limbs, especially after any exertion; bad taste; loss of appetite. The temperature was highest about the same (102.8°) on the three first days. After the eleventh day it never mounted above 99.6°, except on the fourteenth it reached 100°. Was normal on the twenty-first, and then, for six days, kept slightly above that point. This last elevation of temperature may have been due to the patient having unadvisedly moved herself into an adjoining bed. She convalesced slowly, and solid diet was gradually resumed. Was emaciated and weak, and could not walk across the room for some days after getting out of bed.

Let us look at the result of the treatment in these cases, and also see what claim they have to be considered as established.

In Case I, the fever lasted only three days after the ipecac and calomel had been administered. Owing to some negligence quinine either was not given, or else I failed to make a note of it in my record of the case. The patient, a strong and generally healthy man, had resided in Washington a number of years without having shown any susceptibility to malarial poisoning. There are no particular symptoms of typhoid fever present in this history, either during the development or course of the attack, unless we except the tympanitic distention of the abdomen, and the meteorism and tenderness in the right iliac fossa, noticed on the fifth day. Upon what, then, was the diagnosis based? Almost wholly, I must say, on the features presented during the stage of convalescence. The temperature was below normal for almost two weeks after the fever had left. The fever lasted only five days, was not high, and yet he lost over thirty pounds in weight. He was weak, emaciated, and languid. Such a picture, to my mind, is as indicative of a convalescence from typhoid fever as of any other, and the absence of desquamation marks the convalescence of that disease.

In Case II. the fever lasted only six days after the action of the ipecac and calomel. The history of this case develops some stronger diagnostic points. A specific fever: quinine did not arrest it. The attack came on just as the patient’s sister was convalescing from typhoid fever. Her attack was well marked, and accompanied by diarrhea, rose-spots, and delirium. The decline of the disease in his case presented the characteristic fever fall of typhoid. Finally his convalescence was marked by subnormal temperature, emaciation, and feebleness. He was free from fever two weeks before leaving his bed, had a slight relapse, and did not get up again until the temperature was normal.

The case above related to Mary D——, aged twenty and one month. She was taken with the fever on November 2, 1879, after having had the usual prodromic symptoms. Quinine had no effect. The severity of her attack, which had been one of the most acute, presented a marked contrast to the mild symptoms of the two succeeding cases. Her fever lasted twenty-four days, and reached 105°. She had rose-spots, and suffered with a severe diarrhea—passing from four to eight stools per diem during three weeks of her attack. She lost a great deal of flesh, and her recovery was slow. The next, Dr. Chambers, of New York, of which began December 6th. Quinine did not arrest the attack. The fever ceased eight days after ipecac and calomel had been given. Had slight diarrhea, and two rose-spots appeared.

Two weeks after this case had commenced, Case IV. developed. Cinchonism failed to arrest this likewise. Ipecac and calomel administered. A very low range of fever marked the course of this attack; but, with the exception of one day, she was not entirely free of it for twenty-six days. It was highest the first three days, then gradually declined each succeeding day except the eighth and ninth, and after the fourteenth was so slight that it could scarcely be detected without the aid of the thermometer.

If I have given sufficient reasons to justify these cases being diagnosed typhoid, then certainly it must be admitted that the treatment employed had some effect to lessen the duration, and to alter the course, of the fever. And as this treatment is only applicable to cases that come under observation in the beginning of the attack, the result is even more favorable. As we commence to count the days of fever earlier than would otherwise be the case. I have never succeeded in arresting the fever at once. Dr. Chambers, in speaking about a case (p. 129) in which he had had this happy result to follow, says: "It is now nearly two years since I have had a case of fever so decidedly cut short by an emetic; so do not expect it often. But nearly all have the violence of the disease alleviated by that remedy; so that it is never out of place during the first week of the fever."

The case then should come under treatment in the early part of the attack is, I believe, a sine qua non condition of success.

Unfortunately typhoid-fever patients do not generally come into the physician’s hands until too late, unless they happen to follow other cases of the disease that are under observation in the same household. As a rule, they first run through the usual list of domestic remedies for biliousness, malaria, indigestion, worms, and a host of fancied maladies before sending for the doctor.

One of the longest ranges I have had to treat was in which I have attended was that of a case in which the ipecac and calomel powder came too late to check it because of the delay in coming under treatment. The patient, Harry A——, a young man aged nineteen years, had been doing himself for nine days with compound cathartic pills, Dover’s powder, and quinine. On January 5, 1879, I gave him the emetic and purgative powder. He vomited two or three times in half an hour after, had a thin, watery movement in one hour, and two hours later another thin, offensive passage. His temperature at the time was 102.4°; and he had rose-spots and gurgling on pressure in the right iliac fossa. The fever continued in this case until the forty-second day, and pursued a very erratic course. It was highest the fourth week. It was six weeks after the fever subsided before he had regained sufficient strength to leave the house for a ride.

Cases III. and IV, occurred in quick succession in the same household, and were preceded by a typical case of the disease in another member of the family. In fact, if we take into consideration a case which occurred six months before this present outbreak, only three members out of a family of seven escaped having the disease. The first case of the present series developed in the person of Alice D——, aged two years and one month. She was taken with the fever on November 2, 1879, after having had the usual prodromic symptoms. Quinine had had no effect. The severity of her attack, which had been one of the most acute, presented a marked contrast to the mild symptoms of the two succeeding cases. Her fever lasted twenty-four
faithful record of the foregoing cases, to present what
claims they have to be considered typhoid, and to
demonstrate the effect of treatment in altering their course
and in lessening their duration.
— CASE V.—Since having written this paper I have had
the good fortune to be enabled to test the eliminative treatment
in another case of typhoid fever. As it differed in
some particulars from any others, I will ask to present a short record of the case.
On Monday morning, December 31, 1883, I was called
to see N——, a delicate-looking girl, nine years of age.
I obtained from her mother the following history: The
child left Danville, Va., and came to Washington to join
her family some time before Christmas. Twelve weeks
after her arrival she was given a dose of oil, and the next
day one of salts, because of a headache that she had been
complaining of since before leaving Virginia. She did
not improve, and her mother thought she was suffering from
"cold" or "malaria." Thursday evening (the 27th) she
first detected fever. The mother then became un-
easy, because in July of the preceding summer, while
staying in Danville, she had lost one of her children by
a fever which was said to have been malarial at first, but
afterward, as she expressed it, "it ran into typhoid."
She kept the child in bed and administered nine
grains of quinine on Saturday, Sunday, and Monday
mornings. I first saw her on Monday morning about
11 o'clock. Her face was flushed and tongue coated
over its posterior half. Her pulse was 130, respiration
101.8. As examination failed to detect any
inflammatory cause to account for the fever, and
as twenty-seven grains of quinine had already been given,
I felt warranted in ordering the emetic and purgative
powder. At 11.30 she took four grains each of ipecac
and calomel. Vomited a little fluid and mucus and had
a natural movement at 5.30 P.M. At 6 her pulse and
temperature were the same. As the powder had acted
so slightly it was directed to be repeated at 7 P.M. This
time it was with better result—she vomited more freely
and had another stool in the night. There was a more
or less steady continuation of fever for the next six days.
During those days she had epistaxis; several crops of
rose-spots; decided tenderness in the right iliac fossa,
and some meteorism. Sordes appeared upon the lips;
tongue was dry and cracked; bowels regular. Face
flushed, and expression dull. On the evening of January
6, 1884, an abundant crop of fever-spots came out
over her chest and abdomen, and soon on her back. I
gave up all hope of any beneficial effect following the
administration of the powder, and ordered eight drops of
a dilute hydrochloric acid every four hours.
I was surprised and gratified the next morning to find
the temperature down to 99°. The morning temperature
became normal after the 9th; the evening excursions
were slight for three days longer, and after the 12th both
the morning and evening temperatures were sub-
normal. Sordes soon cleaned off the lips; tongue
remained dry and cracked for some days; appetite
returned, and bowels constipated. She is now weak and
emaciated.
Observations of her temperature during convalescence
have been taken daily up to the date of this writing and are:
96.2°, 97.8°, 97.5°, 97.6°, 96.8°, 96.4°, 96.5°,
96.8°, 95.4°, 96.1°.
It will be seen that the subnormal temperature was
lowest on the tenth day after all fever had ceased.
These observations were carefully taken in the axilla,
and the instrument allowed to remain in situ for ten minutes.

THE TIME IT TAKES FOR THE PASSAGE OF A PENNY
THROUGH THE BOWELS.—Dr. A. Ten Eyck, of De
Forestville, N. Y., writes that a girl aged two years,
while playing with some pennies, accidentally swallowed
one. At the end of six months it was discovered in one
of the fecal passages.

Reports of Hospitals.

ST. JOSEPH'S HOSPITAL FOR CONSUMPTIVES,
NEW YORK.

SERVICIE OF C. M. CAULDWELL, M.D.

TREATMENT OF THE COMMONER SYMPTOMS OF PHthisis.

Coughs.—Oxalate of cerium has been used in seventy
cases as a cough palliative, and has rendered excellent
service in relieving this most troublesome symptom of
phthisis. It has one marked advantage over the drugs
usually prescribed in the alleviation of cough, namely,
that of never disturbing either appetite or digestion. Its
good effects were especially noticeable in those cases
where severe paroxysms of coughing, with or without
vomiting, followed the ingestion of food. Where the
cough was troublesome during the day, the drug was
given in ten-grain doses every few hours, but if cough-
ing occurred principally at night, then thirty grains were
given at bedtime and repeated before morning if neces-
sary. When oxalate of cerium alone failed, the desired
effect was often obtained by combining it with chlo-ral hydrate or spirits of chloroform.

Night-sweats.—The following combination of chin-
oide and atropine has been used in thirty cases of
night-sweats occurring in patients suffering with phthisis
in both early and late stages. The annoying and debili-
tating perspirations were not only controlled during the
administration of the drugs, but in a large number of
cases did not return after the treatment had been dis-
continued. The formula used were:

B. Pulv. chinonidin. purific. gr. xii.
Atropia sulph. 8 gr. viii.
M. Pt. capsule No. 2.
Sig.—One the first night, and one three nights later.

B. Pulv. chinonidin. purific. 3 gr.
Pt. pil. No. 12.
Sig.—One pill every night that the capsules are not
taken.

The advantages of this combination over either atro-
pine or quinine, as usually prescribed, are thought to
be: (1) the greater permanency of effect; (2) the free-
dom from unpleasant symptoms often produced by the
other drugs; (3) the comparatively small amount of
medicine necessary; (4) the very moderate expense as
compared with quinine. When this plan of treatment
was contra-indicated, or gave only temporary relief,
pilocin was employed, or in severe cases intragastric
administration in gelatin-coated pellets of one-eighth to
one-fortieth of a grain, at bedtime, and either entirely sus-
pended or greatly diminished the sweating in every case
in which it was prescribed.

Diarrhoea.—Of the various remedies tried in the treat-
ment of over seventy cases of diarrhoea in consumptives,
bismuth was found the most generally useful. In slight
attacks, due to indigestion, etc., it was preceded by a
mild laxative and given in twenty- to thirty-grain doses
every two hours. In the severe forms of diarrhoea, ac-
companied by symptoms of intestinal irritation or inflam-
mation, a combination of twenty grains of bismuth with
one-half grain of opium was given every two or three
hours, with satisfactory results. In a majority of cases.
A number of apparently hopeless cases entirely
recovered from profuse watery diarrhoea when treated with
coto-bark. The formula used was:

B. Extr. coto. fl. 3 gr.
Tr. cardamom. co. 3 gr.
Mucil. acac. 3 ij.
Glycerine 3 ij.
Aq. 3 ij.
Sig. 8 s. ad 24 gr.

M. S.—Half ounce every hour.

Hemoptysis.—The following method of using hama-
melis, or morphine and hamamelis, has given much more satisfactory results in the hemoptysis of phthisis than any other combination of drugs used in this institution. Unlike ergot, lead, veratrum, etc., hamamelis does not disturb the appetite or digestion, but apparently damps the发热 and promotes the healing of the hemorrhages were treated with a single small hypodermic of morphine, followed by one-half drachm of distilled extract of hamamelis, repeated every half hour. Ordinary attacks of hemoptysis were controlled by hamamelis alone, given in the same dose, but at longer intervals. Patients suffering from rapidly recurring hemorrhages were promptly rid of their tendency to hemoptysis when kept upon the distilled extract for several weeks.

PROGRESS OF MEDICAL SCIENCE.

Poisoning by Creasote and Carbolic Acid.—Dr. Pürckhauer publishes an elaborate account of a fatal case of creasote-poisoning, with the remark that only two cases of poisoning by creasote have been previously recorded. In Pürckhauer's case a child ten days old received, as was computed, twenty-four to thirty drops of undiluted creasote. The symptoms were developed almost immediately, and were very like those produced by carbolic acid; injection and inflammation of all visible parts of the body; nausea, vomiting, headache, conjunc- tivation, extremely contracted pupils, difficult respiration, imperceptible pulse, coldness of the extremities, profound coma, and loss of reflex activity. The child did not regain sensibility, was convulsed, and died sixteen hours after the administration of the poison. The necropsy showed lesions similar to those following the administration of carbolic acid—corrosion, local inflammation of the alimentary canal, dark blood, injection of the capillaries, and an all-pervading odor of creasote throughout the body. The same author also relates a not unusual case of poisoning by an enema of carbolic acid in water, where insensibility followed almost immediately on administration. The patient, a girl aged eleven, recovered, the rectum having been very speedily well washed out with warm water, till the washings lost all odor of the poison. Several cases of poisoning by carbolic acid are recorded (Chicago Weekly Med. Review, vol. ii., p. 222, 1883), which are noteworthy in their bearings upon the duration of narcosis and the state of the purely nervous system of the poisoner. Two children, eight and five years old respectively, were recovered from an enema of a pint of water containing seventy drops of ninety-five per cent. carbolic acid. Five minutes later both fell asleep, and slept for twenty minutes. Waking out of sleep, they talked constantly and incoherently, and walked about in a restless manner. Shortly afterward, their gait became unsteady, and they fell to the floor entirely unconscious, with widely dilated pupils, breath charged with the poison, skin bathed in perspiration, pulse full and frequent; and muscular agitation seemed to threaten convulsions. Two hours later, the muscular agitation subsided, coma supervened, and the children could then be aroused only with difficulty. Six hours after the administration of the enema the children became conscious, and vomiting set in, lasting for some hours, after which they rapidly recovered. In another case, where the strong acid was swallowed, the patient also recovered consciousness in about six hours; but here the pupils were contracted, as is usual in carbolic acid poisoning, and not dilated, as in the first related cases.

The Distribution of Poisons in the Body.—Bischke has recently investigated the distribution of poisons in the various organs (Bir. der Chemie, Band xvi., p. 133), selecting for his purpose carbolic acid, chloride of potas- sium, the oxaloids, and the cyanides. In the case of a man who had died a quarter of an hour after taking fifteen grammes of a ninety-one per cent. solution of carbolic acid, 242 grammes of the contents of the stomach and small intestines yielded 0.1711 gramme of phenol; 112 grammes of blood, 0.259 gramme of phenol; 1480 grammes of liver, 0.637 gramme of phenol; 322 grammes of kidney, 0.201 gramme of phenol; 508 grammes of cardiac muscle free from blood, 0.1866 gramme of phenol; 1,445 grammes of brain, 0.314 gramme of phenol; 420 grammes of gluteal muscle, traces of phenol; 125 grammes of urine, 0.0014 gramme of phenol. Thus most of the poison extracted was obtained from the liver, heart, kidneys, and brain. Experiments with chlorate of potash yielded no less definite results, the salt undergoing reduction in the human organism. In the case of a person poisoned by oxalic acid, 358 grammes of the stomach and its contents yielded 0.725 gramme of oxalic acid, and a little oxalate of calcium; 412 grammes of liver, pancreas, kidneys, and heart, 0.0155 gramme of oxalic acid, and 0.95 gramme of oxalic acid as alkaline salt; 100 grammes of blood, 0.067 gramme of oxalic acid as alkaline salt, and traces of calcium oxalate. In other cases, similar results were obtained. In cases of poisoning by hydrocyanic acid, the largest quantity of the poison was found, as might be expected, in the stomach; the liver also occasionally yielded relatively large amounts, and the poison was entirely absent from the urine.

Multiple Cutaneous Ulceration.—In The American Journal of the Medical Sciences for January, 1884, Dr. Atkinson records a case closely related to that rare and remarkable disease known as symmetrical gangrene, but in which gangrene in mass, if we may exclude the secondary destruction of bone, but, on the other hand, rapidly progressive and molecular gangrene. This ulceration, while showing a tendency to affect similar parts of corresponding members and regions, could hardly be termed symmetrical. The ulcers were much more severely than the left, while the left upper and lower extremities were decidedly more affected than those of the right side.

The extent to which motion and sensation were impaired was indeterminate. The child lost the power of locomotion, but whether from diminished nerve influence directly, or from increasing general debility, was not evident. Certainly there was no complete paresis. Similarly with sensation, it was difficult to determine the true condition. That there was abnormal sensation was certain, but whether there was itching or parasthesia was a matter of doubt. There were no scratch marks, nor was any expression of pain elicited upon handling the parts. On the other hand, there was a decided tenderness, and the sensation of pain was decidedly blinded, as shown by insensibility to quite rough usage, and by the violence with which the child bit and rubbed her extremities, even to the production of lesions and the copious discharge of blood. This bluntness of sensation extended beyond the area of lesions, and amounted to a decided numbness. Distinct symptoms of vaso-motor disturbance were not observed; the description of the mother, however, that the extremities became dry and wrinkled, is of significance, though it must be admitted that this was not observed while the child was under treatment. The color of the child's skin would also doubtless interfere with the recognition of vaso-motor phenomena.
Any form of brain lesion, abscess, embolic softening, hemorrhage, tumors, chronic meningitis, if located in the course of the optic fibers or on the surface of one occipital lobe, may produce hemianopsia. The symptom is not due, therefore, to the shock of an apoplexy or embolism; nor to an increase of intracranial pressure; as cases occur in which neither of these conditions is present. It must, therefore, be regarded as a symptom indicating a local circumscribed lesion of one hemisphere, and not a general symptom (such as headache or coma) of brain-disease.

A study of the cases cited leads to the inevitable conclusion that the visual area lies in the occipital region, that the symptoms other than visual cannot be referred to any lesion except to that of the occipital lobe, and that the right occipital lobe receives impressions from the right half of both eyes, and the left occipital lobe from the left half of both eyes.

With these facts in view the question arises, Are there any means of locating the lesion present in a case of hemianopsia? Reference is here made to lateral homonymous hemianopsia. All other forms are due to a lesion of the optic chiasma or optic nerve. A review of the cases and a comparison of symptoms with lesions will demonstrate that this is impossible. Hemianopsia may lie at any point in the course of the optic fibers from the chiasm to the occipital cortex, and in all cases the character of the hemianopsia may be the same. It is only from a study of the accompanying symptoms, therefore, that the lesion can be located. But each of the other symptoms may be due to lesions situated at various points. If it can be proven from a study of the other symptoms that the lesion must be in one definite position, and at the same time a lesion in that position would intercept the visual tract, a probable diagnosis may be reached.

On the Treatment of Hay Fever and Allied Disorders.—In a paper on this subject in The American journal of the Medical Sciences for January, 1884, Dr. Harrison Allen claims that the means of effecting the cure of this hitherto considered incurable disease is simply to overcome the tendency to obstruction in the nasal chambers.

The symptoms of hay fever are always associated with some degree of obstruction of one or both nasal chambers. A cause of this obstruction is dilatation of the blood-vessels. There is no doubt that the local phenomena are in most instances the same, and that the multiformal related symptoms, such as injection of the eye, headache, malaise, asthma, etc., are due to reflex vaso-motor disturbances. But many patients report for treatment who exhibit swelling of the nasal mucous membrane, occlusion of the respiratory passages, and mucoid or semi-purulent discharge, without any of the related reflex phenomena. Yet a third and intermediate group exhibit perhaps a tendency to turgescence of the mucous membrane, together with one or more of the more common constitutional symptoms of typical hay-fever. Indeed, there is nothing peculiar to the disease just named save its sharply defined periodicity, particularly in that phase of it where the periods of recurrence happen to coincide with the time of fruitage of certain plants, or the gathering of certain crops. In a small group of cases, where, in addition, other signs and symptoms become prominent which would invalidate the above proposition, Dr. Allen is inclined to attribute them to mental impression—in some of the varied phases of hysterical or neurotic excitement.

Or the case may be stated in different language, as follows: In an imperfectly defined group of cases of nasal catarrh, a sensation of sudden obstruction of one or both nasal chambers is a constant symptom. This symptom is accompanied by a constant change in the chambers themselves, viz.: engorgement of the membranes over the turbinated bones, producing pressure against the septum
and occlusion of the respiratory passages of the nose. The sensations are recurrent, but vary greatly as to the time of the day or the season of their return. With some pain in the chest are nocturnal, and are associated with the recumbent position; with others, during meals or after meals only; with some they occur in the summer season; with others, yet again, in the winter. The sensations may be confined to either chamber, or be present in both. In aggravated cases they are associated with numerous reflex symptoms, among which may be mentioned lachrymation and hyperesthesia of the conjunctiva, headache, and asthma. Pathology: In regard to obstruction during the summer and autumn report themselves as suffering from "hay-fever;" while those having alternating attacks in the right and the left chambers report with "nasal catarrh." The cases so far studied exhibit one feature in common, viz.: that the inferior turbinate bones lie well above the plane of the floor of the nasal vestibule. In many persons, not the subjects of "hay-fever" and allied disorders, the lower free portion, including, of course, the inferior border of the bone, lies below the plane of the floor of the nasal vestibule, and in ordinary inspection the inferior meatus is out of sight. It will thus be seen that the mucous membrane, which is here the seat of the irritation, is also the most exposed to irritation from external substances, and to changes in the temperature of the surrounding air. The conclusions to be drawn from the study of the cases reported by Dr. Allen may be summarized briefly as follows: 1. That the treatment of all conditions of obstruction in the nasal chambers, no matter from what cause arising, must be successfully carried out by removing the causes of obstruction. If the cause be an overgrowth of bone-tissue, it must be filed, sawed, or drilled away. If it be caused by a deviated cartilaginous portion of the septum, such portion must be reset in a new place. If, as is often the case, it is due to periodic turgescence of the mucous membrane or the resulting secondary hypertrophies, such processes must be destroyed, with the galvano-cautery, by the snare, or by caustic acids. 2. That the treatment of hay-fever and allied periodically recurring nasal affections in no way differs from the treatment of other nasal diseases accompanied by obstruction, and that the treatment may be conducted during an attack as well as in the intervals between any two attacks.

**The Absorption of Fat in Fever and Appetia.**—The influence of the febrile state upon digestion is not yet fully known. A recent contribution to this subject has been made by a Russian physician, Dr. Tchernoff. From a series of observations on the assimilation of fat the author has come to the following conclusions (St. Petersburg Inaugural Dissertation, 1883): 1. A healthy subject assimilates about ninety to ninety-four or ninety-five per cent. of fat of the food given, provided it be present in a form suitable for the action of bile and pancreatic juice. 2. A subject suffering from febrile disease, as a rule, assimilates lesser quantities of fat than the same subject in a healthy state, the difference being on an average 7.2 per cent. 3. The single deviation from this rule is given in enteric fever. When suffering from the latter, the patient absorbs more of fat than when he is convalescent, or quite well. This is especially true in regard to severe forms of typhoid. According to the author, the fact of fat being better assimilated by typhoid patients finds its explanation in the presence of great numbers of leucocytes in the intestines in cases of enteric fever. As a recent work of Professor N. N. Jawarykin shows, leucocytes are "true absorbers and distributors of fat." 4. The quantity of absorbed fat, and the percentage proportion of it in fevers, are influenced by the condition of fat in the body at the time of examination, by the individuality of the patient examined, by the general state at the time of examination, and, possibly, by the admixture of carbohydrates and albuminoid matters. 5. There exists no difference between adults and children in regard to all the propositions stated above. 6. Febrile patients, though their faculty of the absorption of fat is diminished, still assimilate fat in considerable quantity. Therefore, any fears entertained against the administration of fat to febrile patients are groundless. Any avoidance of fat in febrile diet would be unjustified: fat is as necessary for the diseased as it is for the healthy.

**Rheumatism and its Allies in Childhood.**—Dr. Thomas Barlow thinks that it is impossible to define systematically what is meant by rheumatism, and at present it is best to agree on what we consider to be a typical case of rheumatic fever, such as: acute attacks, relapses, sequelae, and recurrences of that affection. Attention is drawn to an affection about which there is great difference of opinion—viz.: scarlatiniform rheumatism. Rheumatism is often spoken of as a sequel of scarlet fever, but it is more often a complication than a sequel. Often in scarlet fever swellings in the sheaths of the tendons are noticed, and joint-structures become implicated; these symptoms subside very rapidly under the influence of salicylate of soda. In rare cases the effusion in one joint at least becomes purulent. There is also in scarlet fever sometimes an affection of serous membranes parallel to what is found in rheumatic fever, but in scarlet fever these effusions often become purulent. Speaking of the linien-lehrer in relation to the case of the patient, Dr. Bateman does not consider that erythema nodosum is closely related to rheumatism, much less convertible into it; but with regard to erythema marginatum and erythema papulatum, there seems more satisfactory evidence to prove that they are related to rheumatism. Urticaria and purpura are in rare instances also related to rheumatism. Dr. Bateman sums up his remarks on the relation between chorea and rheumatism: 1. Chorea should be looked upon as a symptom rather than a disease. 2. We are more justified in saying that chorea is always rheumatic, than in saying that delirium and hyperpyrexia are always rheumatic. 3. Chorea occurs so frequently in connection with rheumatic symptoms, both in combination and in alternation, that we are justified in provisionally regarding it as itself often a rheumatic symptom. Salacin compounds are not often of much use in the rheumatism of infants, as these compounds are most useful in cases of joint-effusions with pain and fever; whereas a great deal of the rheumatism met with in children is inflammatory, being caused either by ill-digested food affection, slight pain, and fever. London Medical Record, December 15, 1883.

**Acute Pneumonia.**—The report of the Collective Investigation Committee on pneumonia, although only provisional, contains a great deal of interesting matter, and is based on an analysis of 350 cases. The general result of the pathological inquiry is thus summarized: "We think the evidence before us is insufficient to support the doctrine that pneumonia is a specific fever, whose chief local manifestation is in the lungs. Like other respiratory fevers it depends on the differences between the resistance of the person attacked, and the resistance of certain states of the weather; and, apart from all else, the great regulator of its frequency is season. It may be taken for certain that it confines no protection upon the individual, but rather an increased liability to future attacks. It appears to have no direct association with any specific or conveyable disease, and its near alliance with diarrhea is in striking contrast with its infrequency in connection with diphtheria. Instances of pneumonia undoubtedly occur, which are apparently 'pyogenic,' but those which have this origin are not otherwise separable, so far as we see at present, from others which are obviously due to exposure. Epidemic pneumonia, as judged by the cases here under reporting, is partly explained by atmospheric conditions, and in part by other agencies generally prejudicial to health." British Medical Journal, December 1, 1883.
RECENT DEPARTURES IN THE TREATMENT OF PHthisis.

It is not many years since Dr. Hughes Bennett stated with emphasis that all attempts to treat phthisis locally had proved a failure. In saying this he undoubtedly expressed the opinion very generally held at that time.

Since the attempt was initiated by Koch, however, to establish phthisis as a parasitic disease, its therapeutics have been studied from a new standpoint, and there are now two distinct schools of workers. The one is laboring to find some means of checking phthisis by destroying its supposed parasitic cause; the other still maintains that a constitutional dyscrasia is the main thing for the therapeutists to consider, and that attempts to treat this disease by directly destroying the bacilli are futile and impracticable. The profession in general is still in harmony, and properly, with this latter view.

One of the leaders among those who deny the value of the antiseptic treatment of phthisis is Buchner, who has formulated his views very clearly. An infectious disease (and phthisis in most of its forms is surely that), says Buchner, is a battle between the body-cells and the micrococi. The result is inflammation and fever. The therapeutist may help the organism in the contest by strengthening the force of the cells, but he cannot destroy or weaken the micrococi without equally injuring the tissues within which they are imbedded. Hence, in phthisis, he recommends nutritive stimulants, not antiseptics. Among the best of these stimulants, he believes, is arsenic, and this drug seems likely to be brought forward again into prominence in the treatment of phthisis.

Arsenic is by no means a new remedy in this disease. It was recommended by Dioscorides centuries ago. It was again recommended by Beddoes early in the present century. Trouseau used it on a large scale, as did also Héred, Mottard Martin, and several other French physicians. It has not been largely tried by English observers. Drs. Sanger and Leared commend it, while Williams, Ringer, and Phillips speak of its value in qualified terms. Dr. Bartholow says that he has no single drug of equal utility in the chronic forms of phthisis, but it is not serviceable in caseous pneumonia.

Following the suggestions of Buchner, Drs. Kempner and Zadeck, of Berlin, have lately employed arsenic in a small number of cases with good, though not brilliant results. (Wiener Med. Wochensch., No. 4, 1884), while Stentzig, of Munich, was less successful. At the recent meeting of the New York State Medical Society, Dr. A. Jacobi (vide page 199) expressed a favorable opinion upon the action of the drug, and in the discussion upon his paper, Dr. Drake said that arsenic was much used in Bellevue Hospital in chronic phthisis.

It is plain that the exact value of this drug has yet to be determined. That it is of some potency is unquestionable, but it seems to be only a symptomatic remedy, relieving cough and fever, increasing the appetite and bodily weight, without much improving the local pulmonary lesions. Trouseau insisted that if it did good it would do at once, and, furthermore, that it was rather a conservator of tissue than a stimulant to growth.

As regards the anti-parasitic treatment of phthisis some important work has been done.

It has been shown by a number of persons that the tubercular virus is not destroyed with the same ease as the septic germs. According to Parrot and Martin (Rev. de Méd., No. 10, 1883), sublimate solutions (1 to 1,000), salicylic acid solutions (1 to 500), carbolic acid solutions (1 to 20), resorcin, solutions of bromine (1 to 1,000), and oxygenated water, do not destroy the infective power of the tubercle virus; a temperature of 106° to 120° C. was, however, sufficient. Dr. Niepce has recently announced (La France Médicale, No. 14, 1884) that sulphured hydrogen is a destructive agent.

As an anti-parasitic remedy in phthisis, iodoform has perhaps attracted most attention. Professor Semmel was one of the first to call attention to the value of iodoform in phthisis. His recommendations were quickly followed by a number of other Italian physicians (La Spallanzani, January and February, 1883). It was stated that incipient phthisis was very often cured by it, the drug acting as an "alterative," antiseptic, and anesthetic. Dr. Dreschfeld, in 1882, reported good results from iodoform, and repeated his commendations of it a year later (British Medical Journal, April 28, 1883). But the first one to use iodoform efficiently as a direct local antiseptic was Sormani, who has published his results in the Annal. Univers. di Med. e Chirur., September 8, 1883. It must have been apparent to any one having even an elementary knowledge of physiology, that the attempt to destroy germs in the lungs by ordinary inhalations or sprays is utterly irrational and useless; for inhaled fluids are only carried a short distance into the bronchi, and never reach the alveoli at all. Sormani, having this fact in view, devised an apparatus for carrying by means of compressed air an ethereal solution of iodoform deep into the lungs. That the drug was thus carried even to the alveoli he proved by inhalation experiments upon calves. Sormani reports only three cases of phthisis in the second stage treated by his method. In each instance there was immediate improvement in the symptoms, and marked gain in bodily weight. On the other hand, there was no especial change in the local tuberculous processes. The sputa also continued to contain bacilli, though in smaller numbers. The sputa injected into guinea-pigs appeared to be lessened in virulence, but was still actively infective.

From a review of the foregoing, it will be seen that the antiseptic treatment of phthisis has yet to gain a foothold in therapeutics. While inhalations may occasion-
ally do some good in relieving symptoms and lessening the complicating bronchitis, we must still use our strongest efforts to help the cell rather than to kill the bacillus.

LOCAL ASPHYXIA AND PALUDAL GANGRENE.

The influence of paludism in producing local asphyxia and gangrene has recently been the subject of a series of very instructive papers, by MM. Petit and Verneuil, in the Revue de Chirurgie, Nos. 1, 3, 6, and 9, 1883. Local asphyxia, stasis of blood in the capillaries, is a phenomenon attending every febrile paroxysm, and may in some cases acquire considerable gravity. As a matter of course, it is to the vaso-motor and vaso-constrictor system that we must look in explaining the various degrees of oligemia, ischemia, and capillary stasis observed in the first stage of paludal fever, and in certain affections of paludal origin. The muscular system being under the control of the nervous system, the vascular apparatus is modified in consequence, and the anatomical elements and tissues are affected.

The vascular spasm presents itself in two different ways; sometimes the peripheral capillaries are almost completely exsanguinated, and the skin is pale; again the whole surface of the body, especially the nose, ears, fingers, and toes are livid, showing the state of stagnation and non-oxidation of the blood in the smaller capillaries. With a high degree of these two morbid states of syncope and asphyxia local gangrene occurs. Of local syncope, however, we shall say nothing at present. As regards local asphyxia, it may be contemporaneous with the febrile access, or it may be chronologically independent. In the first case the circulatory troubles precede the sensations of chill, or coincide with them, or they appear during the sweating stage. In the second, ischemia succeeds the fever, replaces or alternates with it, but itself is apyretic. It may appear in subjects who have had attacks of intermittent several years before, more or less intense and rebellious.

In studying the pathogenesis of paludal ischemia it is not difficult to recognize the combined action of the nervous system, and the contraction of the vascular walls in producing these circulatory troubles, and to see in them a simple prolongation or exaggeration of the initial stage of the febrile access, or the cold stage. But it is necessary to inquire why this stage, ordinarily short, should persist for so long a time in certain cases, and appear isolated in others, without fever or sweating. As in other questions of pathogenesis, an explanation is almost impossible. It should be remembered that as compared with the great frequency of intermittent affections, local asphyxia is very rare. In a paper on paludal neuralgia, Verneuil has said that three causal elements were probably necessary: paludism, as a poison or dyscrastic agent, rheumatism or arthritis as a constitutional agent, and cold, humidity, or sudden changes of temperature as meteoric agents. In all probability this remark is applicable in the consideration of paludal asphyxia, and from the great rarity of true local asphyxia we may suppose the necessity of a complex association of pathogenetic agents. The local influence of cold is often observed, as is the influence of the very variable constitutions of the subjects affected. Paludal poison seems never of itself to produce local asphyxia, for the latter is very rare, and is never seen in the epidemic state; very exceptional in the first stages of paludal intoxication, it is only seen in chronic sufferers, or in the victims of rebellious or violent fevers.

In 1859, Moutet reported a case of gangrene of the penis caused by intermittent fever, and quotes the two cases of sphecusus of the penis reported by Marjolin. Moutet concludes his paper with the observations that this gangrene is one of the phenomenal expressions of the pernicious character of the fever, and that its tendency is to invade peripheral rather than deeper parts. Since 1860 many cases of gangrene of various parts from paludism have been recorded by foreign observers, and it is not a little singular that no more attention has been paid to the subject in our encyclopedic works. The remark of Rondot, however ("Thése," 1880), that paludal intoxication is not a well-recognized cause of gangrene, seems a little premature. But little seems to be known of the subject; and the rôle of paludism in the pathogenesis of gangrene, the forms and prognosis of the affection, are still hypotheses.

As regards form, paludal gangrene is either associated or independent, secondary, or primary. The associated or secondary form follows wounds, or local injuries, the various phlegmasias, and certain cutaneous affections. Obédénaire reports a fatal case of gangrene of the genital organs in a girl of six years, following traumatism during paludal splenitis. Similar cases are reported by Anguict, Moutet, and others. Comaneano, an assistant surgeon in the Turco-Russian war, mentions the frequency of wound complications in paludal subjects. Of thirty wounded, of which he had charge at one time, twenty-two recovered without accident; in eight, however, the wounds showed a marked tendency to phagedæa and gangrene. The eight were all old subjects of paludism. The smallest wounds are sometimes sufficient to cause gangrene in these subjects. Verneuil and Petit state that Haspel has abandoned venesection in intermittents because the resulting wounds were so liable to become inflamed and take on a gangrenous process. We may remark that rational therapeutics and common sense should have forestalled the lesson taught by gangrene in his cases. George Yeates Hunter has observed that ulcerations after hypodermatic injections of quinine in intermittent fever are extremely frequent. The late Dr. F. D. Lente has reported similar observations. We can only recall one instance of ulceration in our own experience after such an injection, which was in the case of chronic paludism, though it is well known that such ulceration after the injection of quinine is quite common, unless the water be boiled while making the solution on the spot.

Paludal gangrene presents, as regards its situation, two important characteristics: it more often attacks the terminal extremities of the members, fingers, toes, the salient points of the head and the male genital organs; it is almost always symmetrical, and when attacking median organs, usually invades both sides. These two characteristics are especially seen in cases of spontaneous gangrene, but are absent when there is a complicating previous pathological state, as traumatism or inflammation. The seat of the process is often determined by the previous state of the organ, conformably, as it would seem, to the theory of least resistance. Be
side the symmetrical and unilateral forms, Graefe and Moty have described a variety of gangrene occurring in irregular patches (en plaques).

There is nothing which would warrant us in attributing a particular symptomatology to paludal gangrene; the symptoms vary according to the relation in which the spheneculus stands to the febrile attack, or according as there is some pre-existing disease, as bronchitis, pneumonia, etc. It may be said to manifest itself under three sets of conditions: 1, during the course of intermittent fever; 2, in subjects of former chronic paludism, but for some time exempt from an attack; and, 3, in such cases as are included under the second head, but attacked by a disease in the course of which there may be fever. In the first and third cases it is seen that there is a febrile movement; in the second, there is no elevation of temperature. The latter, though, is very uncommon, for the reason that gangrene, as other affections occurring in paludal subjects, is extremely liable to awaken the sleeping enemy and bring on an attack of intermittent. The temperature may be normal, subnormal, or febrile during the gangrenous process. The state of the sensibility is very variable and seems to be independent of the febrile phenomena. Pain is not always present, but when it is, cannot always be made to disappear by quinine. As to its progress, the gangrene may be continued, remittent, or intermittent, and, as is the case with other forms of dry gangrene, is usually circumscribed. Coincident with the peripheral disorders there may be attacks of cerebral apoplexy, as in two cases reported by Larché and Moty.

The duration of the disorder varies with its volume and the number of parts attacked. A grave form of gangrene of the mouth, or phleghmonous gangrene in a cachectic subject, may terminate in a few days. When peripheral organs of small volume are attacked by the dry form, the duration is regulated by the rapidity with which the eschars fall and cicatrization takes place. There being, as already stated, a marked tendency to circumscription, the usual termination of paludal gangrene is in recovery, but death seems to be the rule in noma, and in anginous and pulmonary gangrene, and is rather to be attributed to the intense fever, the visceral lesions, and other complications, than to the gangrenous process itself. As a rule, it is not difficult to diagnostic this gangrene. Nevertheless, in cases of prolonged ischemia or of local asphyxia, the diagnosis may remain doubtful for some time. The determination of the paludal nature of the affection, however, is not always without difficulty. Because there is a history of malaria at some previous period, we are not certainly justified in ascribing the affection to a paludal origin; but if the subject is young, a male, and has already had attacks of fever; if the gangrene is symmetrical and peripheral, dry and circumscribed; if preceded by more or less prolonged, circulatory troubles, and is intermittent or remittent, the diagnosis may be considered established. And in any doubtful case the diagnostician should bear in mind the hybrid nature and protean forms of malaria. Of course there will be no little difficulty in establishing a diagnosis when diabetes or alcoholism complicate the paludal intoxication. The close relation between paludism and diabetes has been frequently pointed out, and the occurrence of sugar in the urine of paludal subjects attacked by gangrene is far from rare. Besides diabetes, alcoholism, atheroma, cardiac, renal, and pulmonary affections may cause such general or local modifications as to favor gangrene.

The prognosis of paludal gangrene is generally favorable, though some cases prove fatal. Our main therapeutic reliance is in arsenic and quinine, with local treatment. Exposure to cold increases the liability to an attack. The pain is, of course, to be controlled by opium. The indications for surgical intervention are the same as in gangrene from any other cause. When occurring in the mouth, antiseptic injections—subcutaneous or submucous—should be resorted to, as there is reason to believe that in this locality the affection is of bacterial origin.

THE ORIGIN OF THE NORMAL PERCUSSION NOTE OF THE THORAX.

Numerous theories have been advanced respecting the manner in which the normal percussion note is produced in the chest. Some writers, among whom are Williams and Mazonnii, have referred the sound to the vibrations of the thoracic walls. Others, as Skoda and his followers, believe it to be produced in the air contained within the lungs, while Ninich regards it as arising in the pulmonary tissue itself. More recently, authors have been inclined to regard the percussion note as resulting from the combined effect of all these factors. Dr. Raimondi Feletti has recently published the results of a number of experiments undertaken by him to further elucidate this interesting subject (Revista Clinica, Nos. 7 and 8, 1883). He endeavored, as far as possible, to separate the three above-mentioned factors, and to determine the share of each in the production of the sound in question. He concluded that the thoracic percussion sound is caused, primarily, by the vibrations of the chest-wall, or rather, of the ribs, intensified by the synchronous agitation of the air within the lungs. The action of the pulmonary tissue itself is only to disturb the regularity of these consonant vibrations, especially those of the air contained within the lungs, and thereby to modify the note of the percussion sound. This modified sound, then, is the normal percussion heard over healthy lungs, and physicians are familiar with its still further modification in the various abnormal conditions brought about by disease.

THE SECOND SOUND OF THE CAROTID ARTERY.

The assertion, first made by Weil, that the second (arterio-systolic) carotid sound was caused, in part at least, by the closure of the pulmonary valves, and was not to be regarded wholly as the transmitted aortic second sound, has received little or no mention, even in the most recent works on this subject. Weil based his theory upon the known transmission of the murmur of pulmonary stenosis, and also upon the (not constant) increase of the second carotid sound in the case of increased intensity of the second pulmonary sound. Dr. C. Bettelheim, having made a number of observations to determine this point (Centralblatt für Klinische Medicin, No. 47, 1883), now announces the same conclusions. In several cases in which the diastolic sounds differed in intensity and timbre at the two orifices, the
second carotid sound corresponded with that at the mouth of the pulmonary artery, or apparently resulted from a mingling of the two sounds. In one case, particularly, of aortic insufficiency, in which there was a diastolic murmur, he heard two clear tones over the carotid. The existence of the second carotid sound in the case of aortic regurgitation is to be explained, he says, by the fact that in such cases the second sound is transmitted into the carotid from the pulmonary valves.

THE NEED OF NEW PARKS FOR NEW YORK CITY.

We have received the report of the Commission appointed to select and locate lands for public parks in New York.

It is now twenty years since Central Park was created, and since that time the population of New York has increased by a million of souls. The area of public land to each inhabitant is therefore six or seven times smaller in New York City than in all other great cities, as may be seen by the following:

<table>
<thead>
<tr>
<th>City</th>
<th>Population</th>
<th>Park acres to each inhabitant</th>
</tr>
</thead>
<tbody>
<tr>
<td>New York</td>
<td>1,500,000</td>
<td>30</td>
</tr>
<tr>
<td>Boston</td>
<td>400,000</td>
<td>75</td>
</tr>
<tr>
<td>Chicago</td>
<td>600,000</td>
<td>120</td>
</tr>
<tr>
<td>Philadelphia</td>
<td>900,000</td>
<td>160</td>
</tr>
<tr>
<td>London</td>
<td>4,500,000</td>
<td>300</td>
</tr>
<tr>
<td>Paris</td>
<td>2,250,000</td>
<td>420</td>
</tr>
</tbody>
</table>

No large city in the world is increasing in size more rapidly than New York, which doubles its population every seventeen years. Hence, every year the provision for more parks becomes additionally necessary.

It is proposed to add three large parks and several smaller ones to those already possessed by the city. The total area of these additions is 3,588 acres, which will make the entire park area of the city nearly 5,000 acres, or about one acre to every three hundred inhabitants. Even with this supply, therefore, we shall be behind most other large cities.

The main advantage in these proposed parks, from a hygienic point of view, will be their effect in drawing the centre of population upward and relieving the fatal crowding which is now the curse of our city. In the Fourth Ward of this city, the population is packed in at the rate of 240,000 per square mile, and the Sixth, Eleventh, and Seventeenth Wards are nearly as crowded. There is nothing like this elsewhere in the world. Forty thousand persons die in New York City during the year, and nearly one-half of these are young children, while in other cities, with a smaller general death-rate, the proportion of children’s deaths is only one-third.

We welcome, therefore, any measure which will help to remove this stifling pressure that breeds both death and vice, and trust that New York will soon have the proper proportion of breathing space for its people.

COLLECTIVE INVESTIGATION OF DISEASE.

The Medical Society of the County of New York made a new departure at its recent meeting by inaugurating a method of collective investigation of disease. This is certainly a movement in the proper direction and promises useful and practical results. It has been tried with success by the British Medical Association, and has been imitated to some extent on this side of the Atlantic, notably by the Medical Society of New Jersey. We have always considered that in the latter society the reports from the committees of investigation from different counties were the most instructive and practical of any presented at the session. There is no reason why this should not be the case with the new work of the County Society. In order to develop a proper interest in the discussions great care should be taken in the selection of a subject. It should have a wide practical bearing and be within the range of the experience of the general practitioner. The chosen topic hardly meets these ends. Still it may do to start with.

The questions are few and simple, and although not many can answer them, they give an earnest of a system of inquiry and method of pointing a discussion which cannot be too highly commended. It is to be hoped that the members will do their best, even with what they have, and thereby properly initiate a movement which may be followed by other sister societies.

A FRAUD IN TARTAR EMETIC.

The French journals call attention with much indignation to certain systematic adulterations in tartar emetic which have been of late years made. It appears that the manufacture of tartar emetic on a large scale was begun in France many years ago. The drug was sold at five francs per kilogramme. The Germans subsequently took up the manufacture and sold it for three francs, thus destroying the French industry.

But now it is announced by both German and French authorities that this cheap German tartar emetic contains from 41 to 46 per cent. of oxalic acid, and is nearly as much an oxyrate as a tartrate of antimony and potassa.

In the doses ordinarily given the oxyrate may not be dangerous, but the medicinal effects are different, and it is wisely urged that pharmacists look to their stock of tartar emetic, and see whether it be as pure as is supposed.

NEWS OF THE WEEK.

THE MEHARRY MEDICAL DEPARTMENT of the Central Tennessee College, in Nashville, has just graduated eight colored physicians. Thirty-five young negro men had previously been graduated from this school, and it is stated that they have been successful in their work and have been well received and aided by the resident white physicians.

The Medical License Bill, introduced into the Virginia Legislature, has been passed and is now the law of the State. We have given its main features.

The Surgeon-General of the Marine Hospital Service.—Dr. Hamilton appeared before the House Committee on Public Health recently, to answer certain charges preferred against him by Col. Waring, Secretary of the National Board of Health. He not only vindicated himself and his service, but preferred counter-charges which apparently will leave some members of the National Board in an awkward position.

A New United States Marine Hospital.—A bill has been introduced in the House by Mr. James, of New
York, providing for the purchase of property on Staten Island for marine hospital purposes, and another by Mr. Young, of Tennessee, for the completion of the marine hospital at Memphis.

The Origin of the Egyptian Cholera Epidemic.
—The U. S. Consul-General at Cairo has sent to the State Department a carefully prepared account of the epidemic of cholera which appeared last year in Egypt. He attributes its origin to the unrestricted intercourse with India allowed through English influence. Thus he writes: "During the months of May and June of last year there was at Bombay and Calcutta a recurrence of cholera, which had the tendency to assume an epidemic form. The sanitary maritime and quarantine council at Alexandria, having been apprised of the impending danger, and energetically pressed by the Turkish sanitary authorities at Constantinople, proposed some measures and quarantine regulations to be applied to all vessels coming from India. But the English Government, whose influence in Egypt is unlimited, has in several ways prevented the execution of the projects of the above mentioned council of Alexandria, and in consequence every vessel arriving from India had free communication with all the ports of the Suez Canal. This unrestrained and direct communication of Egypt with countries in which cholera prevailed was the real cause of the importation of the disease. Another, and a local cause of the development of this malady and of its rapid spread, was occasioned by the following circumstances. Damietta, where the cholera last year first appeared, is an exceedingly unhealthy town. The exhalations there from decaying matter cause every summer ophthalmitis and dysentery. It is also subject, during spring and summer, to the khamsin, a most oppressive hot wind, which carries with it clouds of dust and sand. When the cholera, which according to the official report, appeared at Damietta on the 21st of last June, in a very short time it soon became epidemic. No remedies were employed. There was a thorough absence of medical attendance, and the poor natives, not knowing how to treat it, obstinately abandoned themselves to fate, and perished by thousands. About the middle of last June a great fair was held at Damietta, which attracted over fifteen thousand visitors from neighboring and distant villages. At the time this fair was held several Hindoos visited Damietta for purposes of trade, and also a certain number of coal-men and firemen, employed on English steamers coming from Bombay. According to authentic sources of information these are the circumstances which favored the rapid development of this insidious disease."

The New York Medical Union.—This is an old society with a new name. The East River Medical Association, having reached its majority nearly, believes that it has outgrown an apparently local name, and has adopted the above. "May it long live and prosper!"

Medical Paris.—At the meeting of the Académie des Sciences, January 21st, M. Gosselin criticised Bert's method of giving chloroform. He thought the apparatus cumbersome and unnecessary. At the same time the scientific facts presented by Bert were of great value. M. Bert defended the utility of his apparatus (which re-

seems that of Clover) and said that cheaper and more convenient ones were now being made. M. Chauveau described his method of cultivating and attenuating virus. At the meeting January 28th, M. Charcot presented a note by MM. Lépine, Eymonnet, and Aubert upon the proportion of incompletely oxidized phosphorus in the urine in certain nervous states. An increase of excreted phosphorus had been noted in apoplectic and epileptic attacks. A similar increase had been observed in fatty degeneration of the liver in phthisis, in puerperal encephalitis, jaundice, typhoid fever, and acute pneumonia. This increase in the urine of partially oxidized phosphorus did not indicate necessarily an increased dis assimilation of nervous tissue.

Medical Vienna.—At the meeting of the Society of Physicians, January 25th, Professor Carl v. Braun, presiding, Professor Ludwig read a paper written by Dr. George Papaisissi, of Athens, in which was described the most specific of all methods of treating diptheria. Of forty-two cases treated by this method only three died. It consisted in the internal administration of the following: B. Liquor ammonii caustici, 1/100 x 2 xij.; aqua destillata, $i j x.;$ syrup. $ss.;$ potass. chlorata. gr. xij. to xvj. A dessertspoonful every hour. Food, stimulants, and, if necessary, an emetic are added. Externally the throat is touched with liquor ammonii caustici, pure or diluted with water. Professor Csinkor showed the liver of a pig affected with actinomycosis. Professor Ober- steiner read a paper upon pruritus hiealitis, a disease which he thought was a neurosis and more frequent than is supposed.

Medical Berlin.—The Berlin Medical Society met January 16, Professor Virchow in the chair. Professor Köhner presented a patient aged fifty years suffering from a rare form of scleroderma. The Society then discussed the supervision of medical practice by the state.

An Infant without Arms or Legs.—A Spanish medical journal states that there has been born in Madrid an infant with neither arms nor legs. In other respects it is well formed and healthy, and is now five months old.

To Check the Secretion of Milk.—Dr. Verrall (British Medical Journal) recommends iodide of potassium, 8 grains, and quinine sulphate, 23 grains, three times a day.

Promoting Cremation.—At the meeting of the Cremation Society of New Orleans, on February 21st, the names of several prominent gentlemen were added to the list of members. Père Hyacinthe sent in his adhesion to the principles of the society. It was decided to proceed to the erection of a furnace on the plan of that in use in Milan. It is believed the City Council will direct the incineration of the pauper dead and all dying of contagious diseases as soon as the society is ready to take the contracts.

Dr. Elisha Harris' Will.—The will of Dr. Elisha Harris, of Albany, has been presented for probate. So much of the estate as is credited to the estate of his wife, Eliza Andrew Harris, is left in equal moieties to the Infirmaries for Women and Children of the City of New
York and the New York Infant Asylum, to provide for the care and treatment of one or more patients. All the personal property and the remainder of the estate of the testator, except his medical, hygienic, and other scientific books and manuscripts, go to the brothers and sisters of the testator. The books and manuscripts are left to the executors to be used as they decide.

The General Association of French Physicians held its annual meeting in Paris on February 3d, the president, Prof. Gosselin, presiding.

Professor Joseph Mascha has received the Order of the Iron Cross from the Emperor of Austria.

The New York Cancer Hospital.—A movement has been inaugurated for the establishment of a hospital in this city for the treatment of cancer exclusively. The institution will be largely endowed, and organized on the basis of a general hospital.

Dr. James B. Hunter, of this city, has resigned his position in the Skin and Cancer Hospital.

Stamping out Pleuro-Pneumonia.—A bill has passed the State Assembly appropriating $50,000 for the enforcement of the act designed to stamp out pleuro-pneumonia and other contagious diseases among the cattle in this State.

Foot and Mouth Disease has been discovered among the cattle in Maine. The animals have been strictly quarantined.

Change the "Index Medicus."—Our remarks upon the necessity of more intelligent methods in editing the Index Medicus have excited a very general commendation. The Weekly Medical Review says: "We have always felt that while the intention of the publication is so praiseworthy, the means of carrying out the intentions were not the best adapted to the end in view. It does seem to us that The Medical Record has struck the key-note to its future existence and even increased usefulness. If it were published once in three months, six months, or even twelve months, it would be much more serviceable to the investigator. It matters little to the investigator what has been done within the last few months, because no observations can be said to have acquired the honor of established facts until a certain amount of time has elapsed, so that they may be viewed from the distance, and the general surroundings more accurately observed.

Dr. Albert Smith, formerly a practising physician in this city, died February 19th, at his home in New Rochelle, in the eighty-sixth year of his age.

Suit against a Physician for Sanitary Neglect.—A Washington physician has had suit at law commenced against him, in which the damages are laid at $1,000, for preventing, or failing to take the proper measures for preventing, the spread of a contagious disease in the family of the complainant. This is narrowing the responsibility of the physician down within close limits. The question will naturally arise in connection with this case, whether it is the function of the physician to prevent disease. If it is, he should certainly be remunerated for such service.

The Hospital Collections and their Distribution.—The final report of the Hospital Saturday and Sunday Association has been published, and it shows that the total collections from all sources amounted to $43,803.69, a sum which has only been exceeded once. The following table shows the source of that part of which came from the churches:

<table>
<thead>
<tr>
<th>Denominations</th>
<th>Number of contributing churches</th>
<th>Amount contributed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Episcopal</td>
<td>49</td>
<td>$11,868.55</td>
</tr>
<tr>
<td>Presbyterian</td>
<td>7</td>
<td>3,399.19</td>
</tr>
<tr>
<td>Methodist</td>
<td>7</td>
<td>350.98</td>
</tr>
<tr>
<td>Reformed (Dutch)</td>

Concerning the very satisfactory increase in the amount of this year’s collection, we cannot add to what we have said before, except to say that the Committee deserve great praise for the energy and perseverance which they have shown in pressing on the movement.
THE PROPOSED NATIONAL PHARMACOPEIA.—The Boston Medical and Surgical Journal discusses the bill introduced by a Pennsylvania Congressman and providing for a national pharmacopoeia to be gotten up by Government medical officers. The Journal thinks a new Pharmacopoeia unnecessary, and says: "The United States Pharmacopoeia is admitted by competent authorities to be one of the best national pharmacopoeias, if not the best, in the world, and, what is very much to the purpose, arrangements were made by the convention which framed it for maintaining it in its present high position and keeping it abreast of the progress of science. We cannot see what is to be gained by another. If the new one is worse than the old it certainly is not wanted. If it is equally as good we shall have the intolerable nuisance of two authorities, unless the Government can compulsorily retire the present work, not on account of age or inefficiency, but on the lowest political ground of making room for somebody who wants the place and has a claim. If the United States want a more authoritative Pharmacopoeia they can easily give the existing one all the authority desired. May we be pardoned the surmise that dis- appointment at the control of the present Pharmacopoeia being no longer almost exclusively vested in the 'great medical centre' has something to do with this new move!"

Dr. Henry L. Sabin, for fifty-six years in practice at Williamsport, Mass., and the oldest trustee of Williams College, died in that town February 25th, aged eighty-three years.

A NOVEL MEDICAL BULLETIN.—Things have come to a curious pass when half a dozen learned doctors find it necessary or agreeable to bulletin in the public press the health of ordinary actors. Mr. Lester Wallack is an estimable gentleman and popular on the stage, but he has now gone to Florida for his health. A report having circulated that he was paralyzed, seven visiting physicians hasten to announce in the daily papers that Mr. Wallack is not paralyzed, but "has a slight halt in his gait as the result of a recent severe attack of rheumatic gout in the hip-joint, which has already, under the genial influences of this climate, almost disappeared, rendering him as supple in his body as he is spiritual in his wit and humor." We do not understand the necessity of all these seven gentlemen testifying that Mr. Wallack is "spiritual in humor," or that he has helped at a church fair. In fact, it was an unnecessary and undignified display of medical names.

Professor John C. Dalton has been elected President of the College of Physicians and Surgeons, New York.

THE SIMS MEMORIAL FUND.

To the Medical Profession and Others Throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting-testimonial than obituaries and eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations, and such as have had the direct advantage of his personal skill are among the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulse to the study of gynecological surgery in America.
NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 21, 1884.

Fordyce Barker, M.D., LL.D., President, in the Chair.

The Differences in Form of the Adult Head.

Dr. John C. Dalton said that a short time ago he became interested in a new method of comparing the differences in the adult human head by means of paper patterns which hatters make when they fit their customers with hats.

He had secured 360 patterns of the heads of persons in various circumstances in life, but all in sufficient possession of their faculties to go to the hat store and get their heads measured for a hat. On comparing these patterns the following points were noticed: first, that there were differences in the general contour of the head; that is, there were long heads and round heads. If too be assumed as the standard width, the medium length will be represented by 125. The mean form, however, included all those between 120 and 130 in length; below 120 being round heads, and above 130 being long heads.

The relation in shape of the head is a symmetrical oval, like the long section of an egg, with the small end in front and the large end behind.

Lack of symmetry existed in nearly all the heads; it was the rule. He had not yet seen an absolutely symmetrical head. In examining brains almost the first thing which strikes the operator is lack of symmetry. First he examines the brain and finds a symmetrical section of any brain; if symmetrical for the general part, it will be unsymmetrical for the cerebellum. Whether made vertical or horizontal, from before backward, or from behind forward, one lateral ventricle will be opened before the other will be entered. The student expects to find the brain symmetrical because books on anatomy illustrate it in that way, but it is not true.

Are these deficiencies in symmetry always in one direction? In the cases which he had examined there was a decided tendency to a preponderance in one direction. There was an apparent twisting of the head; the occiput a little more rounded on the right side, and the anterior part of the temple flattened in a corresponding degree upon the other side so that the entire brain looked twisted. The twist to the left side was most marked. In the 360 cases there were 12 in which the twist was very perceptible, and of these 9 were twisted to the left and 3 to the right.

In the 360 patterns there was a preponderance of long heads over round heads—ten per cent. round heads, and twenty-five per cent. long heads.

Suppose we have two brains with differences in form, or one brain with differences in form of the two sides, does not this imply exaggeration or deficiency of certain parts of the brain which are endowed with special functions, and consequently there are differences in the operations of the nervous centres? It might seem so, and yet he was not at all sure that such an inference legitimately followed the observation.

All things considered, the depth of the convolutions, etc., Dr. Dalton thought it must be concluded that the two sides of the head may differ the one from the other, or two heads may exhibit differences, and yet the essential parts of the brain, so far as the direct working of nervous centres is concerned, are precisely the same.

The Parsonsian Paper Patterns at some time or twenty years ago there was considerable discussion in obstetric and other journals with reference to the influence of parturition upon the shape of the human head, and possibly the intellectual faculties in later life. He then instituted a series of observations in the lying-in wards at Bellevue Hospital, and his House Staff made the outlines of the heads of 132 infants in two months. It was found that the shape of the head corresponded to the position, and as in about eighty-five per cent. of normal cases the position is the left oblique, there was a bulging out upon the right side of the head, because there was less resistance in that direction, and vice versa.

One of the questions at issue was, did this change in the shape of the head, produced by the moulding of it in the pelvis during parturition, influence the function of the brain afterward? In the investigations carried out as indicated, notes were made immediately after birth, and again at the end of eight days, and it was found that in a large proportion of cases this disproportion very largely, but not entirely, disappeared.

Dr. Barker believed that he could, by the study of the child's head, say whether the occiput presented to the right or to the left, etc., provided he could have opportunity to make the examination within forty-eight hours after delivery; but he would not venture to suggest how much such change of shape influences the performance of brain functions, for he was not quite sure that the form of the head changes in the adult, and even quite late.

Dr. Corning regarded Dr. Dalton's communication as exceedingly important, especially with reference to the view that asymmetry of the head is evidence of insanity.

Dr. Webster asked Dr. Dalton if he had noticed any change in the size of the head in adult life.

Dr. Dalton replied that he had not, but such an occurrence was not at all improbable, as other parts of the body enlarged or diminished in size with the increase in years. He regarded it as extremely probable that the twist which the head of the fetus gets during parturition was one that disappeared, perhaps in a few of the cases; but in a few permanent, yet even then he did not know as it would indicate any deficiency in the brain as a nervous organ. Certainly from asymmetry of the head we could not conclude that there was a corresponding deficiency or enlargement of the brain; it might exist, but it was not certain that it did.

Dr. F. A. Morrow then read a paper (see page 277) entitled

An Improved Method in the Treatment of Certain Forms of Skin Affections.

Dr. E. B. Bronson said that, according to his experience, the gelatine preparations possessed but comparatively little value. The gutta-percha preparations were used much more than the gelatine, and he thought they would supersede the latter entirely. Although protection of the surface was a matter of first importance, a material which could not be readily applied was rather objectionable, and the deliberation also with which the gutta-percha and collodion mixtures could be used gave them an advantage over the gelatine preparations. He concurred with Dr. Morrow in the statement that these methods constitute a decided advance in dermatological therapeutics.

Dr. Jackson had been less favorably impressed with the gelatine than with the collodion and gutta-percha preparations.

Dr. S. Sherwell, of Brooklyn, said he had but little experience in the use of these preparations, although he had employed some of the paints. He could easily see how it might be inconvenient both to prepare and to apply gelatine; and he did not exactly see how either of these preparations could be applied to hairy parts and make them so effective as are the oleates or unguals.

Dr. Morrow said he had not experienced any inconvenience in the use of the gelatine preparation, and with regard to applying gutta-percha or collodion to the hairy scalp, for instance, he had the parts either shaved or the hair closely cut, when any of the mixtures could be applied without inconvenience.
after the beginning of the high temperature which was supposed to be due to milk fever. Theoretically, this process had been in existence some time before that, but yet he was at a loss to know how it could be ascertained that septicemia is present unless there are symptoms to give evidence of it.

Dr. Jacobi said he did not wish to be understood as in the least finding fault with the treatment, but he simply wished to say that undoubtedly septicemia developed before symptoms appeared, and before treatment could be commenced. He claimed to be one of those who were modest enough to admit that it is not always possible to make a diagnosis early enough to save all patients. He also claimed that symptoms must be present in order to make a diagnosis, and that they were not present in Dr. Lee’s case. He also claimed that many cases of septicemia are difficult to recognize because of the absence of one exceedingly important symptom, that is, elevation of temperature. Moreover, septicemia is not characterized by pain, so what is there to guide the physician in making the diagnosis? He simply meant in the following sense: Dr. Lee’s case was one in which, if it had been possible to recognize the symptoms of the treatment would have been adopted earlier, but as it was the intra-uterine injections were resorted to too late.

Dr. Northrup said, concerning the exudation on the lower half of the uterus, that two names had been given to it, but whatever name it might receive, it was composed of fibrin and pus; the same material that is found at the vulva or ostium vaginae, or even upon the cervix, and called diphtheritic and croupous exudation. He remarked that Dr. Delafield made the distinction that an exudate composed of pus and fibrin, which is not due to the specific poison of diphtheria, is croupous. The same as the exudation composed of pus and fibrin which appears in scarlet fever or some of the infectious diseases would be called croupous tonsillitis or pharyngitis, unless the scarlet fever or other infectious disease was complicated with diphtheria.

(To be continued.)

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, February 25, 1884.

S. O. Vander Polk, M.D., LL.D., President, in the Chair.

Dr. Wm. S. Halsted read a paper on THE EFFECTS OF ADDUCTION AND ABDUCTION ON THE LENGTH OF THE LIMB IN FRACTURES OF THE NECK OF THE FEMUR.

He demonstrated, by a series of illustrations, that adducting the lower limb makes it measure less along the line from the anterior superior spine of the ilium to either malleolus, while adducting it makes it measure more along the same line. Moreover, when one limb is adducted the other must be abducted to be brought parallel with it.

In fracture of the neck of the femur, therefore, with adduction, the injured limb might actually measure longer than the sound one; because, first, it is lengthened by adduction, and, second, its fellow is shortened by abduction.

In a case from which he had the specimen, he was enabled to make the diagnosis of fracture by the recognition of these facts. The injured limb was apparently shortened, but in reality, when measured from the anterior superior spine of the ilium to the malleolus, it was lengthened one-eighth of an inch, although shortened one-fourth of an inch along Bryant’s line.

He had also seen another patient with fracture of the neck of the femur and abduction, and the limbs were apparently of equal length. Along Bryant’s line the injured limb measured three-eighths of an inch, but from the anterior superior spine of the ilium to the external malleolus, one and one-fourth inch shorter than the sound one.

In cases in which, measured on Bryant’s line, the limbs were equally shortened, there would be more of a limp when adducted than when abducted. For this reason Dr. Halsted thought the limb should not be allowed to remain in an adducted position.

The paper was discussed by Dr. A. B. Judson, who complimented the author on his careful and accurate study of this certainly obscure point, but one which he thought might not have very great practical importance. He spoke thus because he felt quite sure it could not have a practical importance in cases of hip disease, and it might not in fractures, as it seemed to him, because the anterior superior spine of the ilium was situated so near the point of motion, and the opposite point, the malleolus, was so far away, that the differences in length were liable to be so varied by adduction and abstraction as to lose their practical importance.

Dr. Wyeth thought that efforts at exact measurements had been to a certain degree unavailing, because it had been established that it was the exception to find both limbs of precisely the same length normally.

Dr. Halsted said he did not intend that his method should apply in cases of hip-joint disease, because measuring of limbs is not of special consequence there, and furthermore, if it were, the element of fracture which is permanent would make the point. He simply referred to hip cases because of the apparent paradox concerning the length of limbs, which was well known to orthopedic surgeons.

With regard to the angle being too obtuse to be of practical importance, he thought Dr. Judson was in error, because the principle was usually applied in cases at Bellevue Hospital, and had a decided bearing on the question of diagnosis. Its practical application in diagnosis and treatment was all he designed for it, and not as a method for measuring limbs, mentioned by Dr. Wyeth.

Dr. E. C. Spitzka then read a paper on THE PATHS OF CO-ORDINATION.

Progress in the localization of cerebral functions has followed two different lines of research. The first, whose results became most rapidly popularized, consists in the registration of the phenomena following irritation and disease of limited cortical and sub-cortical areas; the other in the anatomical study of the tracts connecting certain centers with others. The former method is the most satisfactory, as regards the rapidity with which conclusions can be drawn from it; but it also suffers from the imperfection of being a more or less empirical method, as has been recognized by the latest and ablest exponent of cortical localization.

The study of tract development and tract disease, which in the hands of Türek yielded the most positive knowledge of which cerebral anatomy can boast—that is, of the course of the nerve-tract, through which the voluntary control of the extremities passes—has within a decade received a new impulse. Fleschig revealed the course of special nerve-tracts, on the basis of their embryonic development; Gudden and his pupils traced others, through artificial atrophies induced in various animals; and a number of pathologists are annually reporting secondary degenerations and systemic diseases of nerve-tracts in the human brain, thus corroborating the former.

The relation of these two lines of research to each other may be compared to that of two exploring expeditions under the survey of the continent from opposite regions. The one maps out the coast outline and here and there follows up the course of an estuary, the other traces the great water-courses and mountain ranges toward that same coast; but the interior geography of the continent will remain unknown or obscure,
until the two expeditions shall have met and joined the paths they have followed. In the central nervous system we know approximately well the physiological geography of the brain surface; we are also fairly familiar with the course of the spinal tracts, but we have, like the surveyors of new lands, not yet gained a sufficient acquaintance with these tracts and centres. The great intermediate district is in large part a tangled labyrinth of fibres, which it will take many more decades to unravel. But step by step this is becoming accomplished; with every new observation a piece here and a piece there is being isolated, and with each such isolation the field of the unknown becomes restricted and the labor of future investigators by so much lightened. Already we know with mathematical precision the course of the will-tract from the cortex to the extremities, and we are acquainted with the course of certain segments—if not of the entire tracts—conducting visual and special sensory impressions to the cortex. It is to call attention to another segment that I shall occupy your time this evening.

I was fortunate enough to obtain permission to make an autopsy in the case of a private patient who had presented the interesting phenomenon of a pure unilateral ataxia of movement, without paralysis, and which I had attributed during life to a hemorrhagic lesion of the pons varoli. That the diagnosis was confirmed was the least improbable. It had been confirmed by Dr. Seguin. He had dissected it and found it nearly as he had described it, with disorganization of the decussations of the pyramids. He had noticed us in the cord the presence of a decussation in the decusation of the pyramids, and had seen the medulla oblongata in its whole extent. The patient had lived for six years, and the symptoms mentioned persisted till death, with slight modifications. After death an apoplectic cyst was found in the pons, not affecting the pyramidal fibres, but those of the folium (lemniscus). A descending degeneration of beautiful distinctness was traced from the cyst down to the upper fine-bundled, so-called sensory decussation of Meynert, and involved the stratum intermedium, or so-called interstitial layer of Flechsig. Specimens and drawings illustrating the lesion were exhibited. Dr. Spitzka concluded that this case showed the importance of the stratum intermedium, conducted as it was with the nuclei of the columns of Goll and Burdach, was the path of the muscular sense, and that hence the channel of the muscular sense, like that for the voluntary control of the extremities, decussated, so that right-sided lesion above the decussation would produce left-sided disturbance, and vice versa.

Dr. E. C. Scoull had been interested in the paper, because in the report of the autopsy and microscopic examination he thought he was able to more clearly understand cases which heretofore he had regarded as sclerosis of the hemispheres. These were hemi-ataxic, ataxic tremor, with slight impairment of sensibility, and paresthesia, but the cases differed from Dr. Spitzka's in being essentially choreic in their course.

There were some difficulties in accepting Dr. Spitzka's conclusions, arising from experiments which had shown that decussation must take place in the cord. Stab-wounds and tumors also had given evidence in favor of decussation in the spinal cord. Besides there was objection to regarding ataxia as a symptom, Dr. Spitzka having shown that ataxia is a symptom of irritation, without any destruction of nerve-tissue.

Dr. Spitzka, in closing the discussion, stated that he recognized the existence of such a class of cases as those alluded to by Dr. Seguin, but did not believe that his own anatomical examination threw much light on them, as they were probably cortical. It was possible for bined motor and sensory disturbances of the kind described to exist with cortical or subcortical disease. He could not exactly understand the nature of the objection based on Dr. Seguin's statement that ataxia might be due to irritative lesion. If he comprehended Dr. Seguin correctly, he had nothing in mind but an irritative lesion, hence it is difficult to explain it on the basis of a destructive lesion. The same argument would dispose of every sign of focal brain disease; for, as is well known, hysteria apes all of them, while many symptoms may be due either to irritative or to destructive lesion. As to Brown-Séquard's experiment, it had to be observed that for while these experiments showed that the tactile and pain paths decussate in the cord, they distinctly showed that the muscular sense did not follow the same course. Even if it were so, the case he related stood by itself, an evidence that the muscular sense decussated, whatever necessity there might be for assuming a rededuction.

Under the head of "Scientific Communications," Dr. C. E. Nelson offered one on "Biology," already published, and began its reading. On motion, the further reading was postponed until some future meeting.

COLLECTIVE INVESTIGATION OF DISEASES.

Dr. David Webster, chairman of the committee, reported the following questions, and it was ordered that the paper be printed, and sent to the Academy with the request that answers be returned to the chairman on or before March 15, 1884, preparatory for discussion March 24, 1884.

1. "How many cases of intestinal obstruction have come under your observation, and what peculiar symptoms were manifested in each case?"
2. "Have you ever performed an operation for the relief of intestinal obstruction due to peritoneal adhesions, and if so, what was the result in each case?"
3. "Have you treated any cases of intestinal obstruction, partial or complete, when the so-called pathognomonic symptoms, such as scrotal orifice vomiting and obstinate constipation, were absent?"

REPORT OF DELEGATES TO THE STATE MEDICAL SOCIETY.

Dr. C. L. Dana reported that all the delegates were present except Drs. Mandé, F. V. White, Leale, and Hitchcock. Further, that three vacancies in the delegation were created by the election of Drs. Lewis, Lockwood, and Gibney to permanent membership. The report was adopted. The vacancies in the delegation were subsequently filled by electing Drs. L. Emmett Holt, M. Josiah Roberts, and Wm. M. McLaurin.

Dr. A. J. Jardine, chairman of the Committee on Hygiene, made a few remarks and then offered the following resolution, which was adopted:

Resolved, That this Society favors the passage of the act to protect factory children, now before the Legislature of this State.

SCHOOL OF MIDWIFERY—LICENSING OF MIDWIVES.

Dr. P. C. Cole, under the head of "New Business," introduced and read two bills, one to establish a school of midwifery, and another to regulate the practice of midwifery by midwives, and gave his reasons for asking the Society to adopt the following resolution:

Resolved, That the Medical Society of the County of New York approves of the general intent and object of these bills.

The subject gave rise to discussion, and was temporarily disposed of by being referred to a special committee, to be reported upon at some future meeting.

The President appointed as the committee, Drs. W. M. Chamberlin, C. C. Lee,* A. M. Jacobus, and E. L. Partridge.
A resolution was adopted expressing the opinion that
the opium plant is a Government monopoly, and its sale
to the unfortunate Chinese (on whom it was forced at the
cannon's mouth) pours millions into the Indian ex-
chequer.

The pay principle in hospitals is on the increase, and
has been adopted by one of our most richly endowed
metropolitan hospitals, viz., Guy's. Threepence weekly
is to be exacted from out-patients, and several beds re-
served for in-patients who can pay a guinea a week.
As regards the out-patients, the system has, at least, so far
worked satisfactorily. The numbers have not diminished,
and nearly all have been able to pay the small sum de-
manded. The only danger is that the pay system may
cause patients who go who could really afford to con-
sult ordinary practitioners in the neighborhood at small
fees. Many patients who would perhaps have hesitated
before seeking eledemosneus medical aid, may view the
matter differently when asked for a fee, however trifling,
and consider their position different from when receiving
bona fide medical charitable advice. We hope that the
hospitals which have taken up the pay system will be
wary in weeding out unsuitable cases.

The newspapers and journals continue to direct atten-
tion to the unhealthy slums of London, many of which
are veritable plague spots. It is not only in London
that such are found, nor is the evil confined to poor
neighborhoods. Only twelve years ago, smallpox fever
occurred in an porter's house in Cambridge, in build-
ings which had been erected only four years pre-
viously with such care and expense that sanitary defects
could scarcely be dreamed of. Yet such were found.
Bagshot Park and Buckingham Palace are instances of
royal residences which have been tried in hygienic scales
and found wanting. At the present moment a paper
war is raging in the columns of the medical journals, be-
tween Mr. Latham and Mr. Barford, as to the sanitary
condition of Wellington College. Mr. Barford is the late
medical officer to the college, and his recommendations
as to sanitary matters would appear to have been disre-
garded with dire results. Mr. Latham is an engineer and
does the best he can to whitewash matters, but his opin-
on medical matters is obviously not of much value.

HOSPITALS FOR INCURABLES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Your editorial in The Record of the 16th ult.,
on "Hospitals for Incurables," is timely, and calls atten-
tion to a want much felt in all our large cities. I have
nothing to add to what you have so well said, but in this
connection it may not be out of place to refer to one
of the most modest and deserving of Brooklyn's many
charities.

The "Brooklyn Home for Consumptives" is an in-
stitution working in the direct line of your suggestions,
and its history is worthy of being more widely known.

Less than three years ago, a well-known clergyman
of this city sought to obtain for a poor woman suffering
from phthisis, admission to some proper hospital. After
repeated applications and repeated refusals, he eventu-
ally found, to his surprise, that there was no place for
such, except the almshouse. This woman was well
bred, had once been in good circumstances, and now
needed tender care and gentle nursing for the few days
remaining to her. She was in no condition to endure
the tender mercies of the County Poor House.

The clergyman referred to said, laconically, "If there
is no place for such, let us build one." With the
aid of friends he leased a private house, and in a small
way opened a home for three or four consumptive pa-
tients. As the story of his endeavors became known,
he found sympathy and assistance. The house became
too small for the number of applicants, and finally the
premises 219 Raymond Street were purchased and
adapted to the purposes of the "Brooklyn Home for
Army and Navy News.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from February 17, 1884, to February 23, 1884.

PATZSCI, JULIUS H., Captain and Assistant Surgeon. Leave of absence extended one year on surgeon’s certificate of disability, with permission to go beyond sea. S. Q. 43, par. 9, A. G. O., February 20, 1884.

MADDIX, T. J. C., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Meyer’s Springs, Texas. Per Post Orders No. 27, par. 1, Fort Clark, Texas, February 13, 1884.

Official List of Changes in the Medical Corps of the Navy, for the week ending February 23, 1884.

RUSH, W. H., Passed Assistant Surgeon. Detached from the Minnesota, and ordered to duty on board the Dispatch.

HALL, J. H., Passed Assistant Surgeon. To the Minnesota.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending February 26, 1884:

by Peter Redfern, M.D., F.R.C.S.E., Professor of Anatomy and Physiology, Queen's College, Belfast.

Visitors going from America to attend this meeting can travel by any of the following routes: 1. A Cunard steamer will leave New York on Saturday, July 12th, and on Saturday, July 19th; due at Queenstown about July 20th and July 27th. 2. An American steamer will leave New York on Sunday, July 13th, and on Sunday, July 20th; due at Queenstown about July 23rd. 4. An Allan steamer will leave New York on Saturday, July 12th, in London next day, July 19th; due at Queenstown about July 26th or 28th. 5. An Anchor steamer will leave New York on Saturday, July 12th; due at Queenstown on July 29th. 6. A White Star steamer will leave New York on Saturday, July 12th, and on Saturday, July 19th; due at Queenstown about July 20th and July 27th. 3. An Italian steamer will leave New York on Tuesday, July 13th, arriving in Queenstown about the following Thursday week, July 24th; (6) Boston on Saturday, July 19th, reaching Queenstown the following Monday week, July 28th.

Meeting of the International Medical Congress at Copenhagen.—The time of the meeting of the British Medical Association at Belfast has been fixed so as not to interfere with the International Medical Congress, which is to take place in Copenhagen, during August. A White Star steamer will leave Hull, England, on August 2d and 9th, for Copenhagen; and on August 5th a steamer will leave Leith, Scotland, for Copenhagen. Both these places, Hull and Leith, can be reached on any day by leaving Belfast on the previous evening by the cross-channel steamers. Visitors, after attending the meeting of the British Medical Association at Belfast, will have ample time to travel to Copenhagen for the Congress.

Communications in reference to the meeting of the British Medical Association at Belfast to be addressed to the Hon. Local Secretaries, John Moore, M.D.; Alex. Dempsey, M.D.; John W. Byers, M.A., M.D.

The Diagnosis between Belladonna Rash and Scarlatina.—Dr. Selden B. Sperry, of Delafield, Wis., sends us the history of a case illustrating, as he believes, two important points in the differential diagnosis between scarlatina and belladonna rash. He was called to see a girl, aged three years, who had for two days suffered with a sore throat. He examined her, found no patches, and thought she was suffering from a pharyngitis. A few days later the mother returned and said her daughter had been given belladonna in one-minim doses every hour. Dr. Sperry writes: “She went to bed and asleep at her usual bedtime. About eight o'clock the father came after me, saying the child had broken out with scarlet fever. I went to see her immediately and found her sitting up crying, with intense irritation of the skin. Her face was as red as a thoroughly developed case of scarlatina. Her body was red, but not as much as her face, and more than the extremities. The eruption was decidedly punctuated, a point I was careful to look into, because Bartholow states that it differs in that respect from the rash of scarlatina. She had no chill. Temperature, normal; pulse, 65. Her health was better than worse than I expected. I ordered her washed with a weak solution of boric acid, and gave her a teaspoonful of syrup of Dover’s, and she was all right in the morning. She had taken four doses, and the eruption did not appear until she was in bed.”

A Man with Three Testicles.—Dr. H. H. Williams, of Johnstown, Pa., sends us the history of the following unique case: “I was consulted a short time since by a young man, aged twenty years, with reference to a lump in his scrotum, which he said had been there ever since he could remember, and that it had never given him any trouble, but that he was anxious to know concerning its nature. Upon examination I found what is evidently a third testicle. His scrotum is quite large and his normal testicles measure two and a fourth inches in their longest diameter, while anterior to the left one is a third testicle, half as large, freely movable, and having a distinct cord of its own. Upon squeezing this testicle he experiences precisely the same sensation as when the others are squeezed. Whether it will interfere with his getting married, I assured him it would not, but told him to look out for triplets.”

Professor von Bergmann at the Operating Table.—A correspondent of the Medical and Surgical Reporter writes of Professor von Bergmann’s method of operating as follows: “The most scrupulous attention is paid to cleanliness in the hands and finger-nails of the operator and assistants. After a thorough washing the hands are dipped in a solution of corrosive sublimate, 1 to 1,000. This was repeated several times during the operation, and the person of the patient around the point of incision was also similarly washed and treated. Before and during the operation a spray of carbolic acid solution, 3 to 100, continuously played on the part operated on, covering surgeons and nurses, as well as patients, with a fine drizzle. All operating instruments and ligatures are kept in an antisepic solution during the operation, except when in use; the instruments lying in the carbolized preparation. The sublimate solution is Professor von Bergmann’s favorite antiseptic. He first introduced it six years ago at Wurzburg. The operating-table is covered with a heavy sheet of rubber, one-half inch thick, which is easily and thoroughly cleaned and kept free from septic infection. Chloroform only is used. It is administered by means of a piece of flannel cloth stretched over a wire conical about the size and shape of a very small bowl. Patients are not allowed to eat on the day of the operation, before its performance. Nausea is comparatively rare, and deaths on the operating-table very rarely heard of. The head of the patient rests on a cylindrical air-cushion, which offers suggestions of convenience and cleanliness. The surgeon applies the ligatures himself. Everything was invariably clean. The iodine which an American seems used with such astonishing freedom, not infrequently—according to Berlin physicians—produces delirium, and is even charged with more serious results. Dr. Fehelesen, one of Professor von Bergmann’s assistants, is continuing his experiments with the bacilli of erysipelas and inculcation with the cultivated poison, notice of which was taken editorially in the Reporter several months since.”

When not to give Chloroform in Parturition.—In a paper read by Dr. Davis before the Eastern District of the Southeastern branch of the Medical Association, he lays down the following rules to be observed in not giving chloroform during labor: 1. Never give it to a woman who has a tendency to flood during every confinement, or to those who have great relaxation of fibre, or weak, anemic women in their eighth or tenth confinement, except for necessity. 2. Do not give it where labor is complicated with severe vomiting, or with acute heart or lung trouble unless there be an imperative demand for it. 3. It should not be given to complete anaesthesia except for operations, convulsions or spasms of the cervix, and then one person should devote his entire attention to it. 4. The inhalation should be stopped directly the pulse becomes weak or the respiraton irregular. 5. Do not give it if there be grounds to fear a fatty or enfeebled cardiac wall. 6. In all cases where it has been given, there should be extra care to prevent post-partum hemorrhage. —The Obstetric Gazette.

A Ready Means for Removing Foreign Bodies from the Throat.—Dr. M. A. Veeder, of Lyons, N.Y., writes: “A loop of ordinary suture wire, which may be readily bent in any shape desired, forms an available means of hooking such articles as pins and needles out of the throat, and has the merit of succeeding some times where more elaborate contrivances have failed.”
Malaria.

By GEORGE M. STERNBERG, M.D.

MAILLOU', in his "Traité des Fièvres Intermittents," concludes his enumeration of the various hypotheses which have been advanced to explain the etiology of the malarial fevers, with the following quotation from Monfalconn: "To know that we know nothing is a great deal; we are then much nearer the truth than when we mistake for this latter, erroneous hypothesis."

The earlier medical authors seem to have considered it their duty to explain all things, and they apparently had as great an abhorrence of a confession of ignorance as nature was said to have of a vacuum. It is only within comparatively recent times that we meet with such ingenious statements as the following. Professor Bartlett, in his "Treatise on Fevers" (1847), says: "The essential, efficient, producing cause of periodical fever—the poison whose action upon the system gives rise to the disease—is a substance or agent, which has received the name of malaria, and march miasm. The nature and composition of this poison are wholly unknown to us." (p. 346).

Professor Geo. B. Wood, in his "Practice of Medicine," says: "Of the precise nature of miasmata nothing certain is known" (vol. i., p. 161).

Aitken says: "The poison in the absence of any better name is known as 'malaria'; and as physicians have only inferred the existence of such a poison, not a particle of knowledge has yet been obtained as to its nature and source." ("Science and Practice of Medicine," vol. i., p. 473).

These statements, made by three of the highest medical authorities of modern times, show a great advance in the direction of truth, for, as Monfalconn says, "to know that we know nothing is a great deal," and so long as we have not acquired this knowledge we are not at all likely to reach the truth, for there is no incentive to engage in those laborious experimental investigations by which modern science seeks to solve etiological problems which have not been settled by the speculations of medical philosophers in the past, and which there is no reason to suppose are incapable of solution by any other than the experimental method.

But the most recent of the authorities above mentioned penned the confession of ignorance which we have quoted more than fifteen years ago, and during the interval numerous investigators, in various parts of the world, have undertaken to apply the experimental method to the solution of etiological questions; and in the case of several infectious diseases of man and of the lower animals have demonstrated very conclusively that these diseases are due to the multiplication within the body of the infected individual of parasitic micro-organisms known under the general name of bacteria. A similar explanation has been given of the etiology of the malarial fevers, and numerous investigations have been made since the time of Bartlett, of Wood, and of Aitken, which

"1 Read at the meeting of the American Public Health Association, Detroit, Mich., November 15, 1883."
somewhat numerous specimens of blood which I have examined from malarial fever patients, either the bacillus of Klebs and Tommassi-Crudeli, or the parasite described by Lavaran. It is but fair to state, however, that I have had but one or two opportunities for obtaining blood during the cold stage of a malarial paroxysm, and have never punctured the spleen to obtain a specimen for examination, my samples having been invariably obtained from the end of the finger.

In view of all this negative evidence, it is not my design to bring discredit upon the observations of the distinguished Italian physician, Tommasi-Crudeli, or upon those of his countrymen Cuboni and Marchiafava, who report that they have found the so-called bacillus malariae in the blood of persons suffering from malarial fever. I do not doubt that bacilli have been found by these gentlemen, as referred. But I would call a three-person fact that the first account published by Marchiafava related to the finding of bacilli in the blood, lymph, spleen, etc., of three persons, who died of pernicious fever. As I have pointed out elsewhere, the finding of micro-organisms in the blood and tissues, obtained post mortem, especially in warm climates, cannot be taken as evidence that the same organisms exist in the blood, especially during the earlier stages of the disease, at which time it should be constantly and invariably present if it is the cause of the morbid phenomena which constitute the disease. But if we admit that the bacilli in question were not developed post mortem we are met by two questions: First, do they bear any relation to the etiology of the disease? And, with respect to that view should be one of reservation. Second, is this pernicious fever of the Italian physicians identical as to its etiology with the fevers recognized as malarial in our own country? The writer has long suspected that the continued pernicious fevers of the Roman Campagna, and of other parts of Italy, differ essentially from the ordinary intermittent and remittent fevers of this country. For no other reason than that element, in a certain proportion of the cases at least, there is another etiological factor, to which the continued and pernicious form of development manifested by the morbid phenomena must be ascribed. We know that malaria may be associated with the specific poison of typhoid and of yellow fever in such a way as to produce typical forms of these diseases. In this sense it is highly probable that the Roman fever is in truth one of these mixed or hybrid forms of disease. In this case the bacillus of Klebs and Tommasi-Crudeli, if it has any etiological import, is probably the factor to which the continued and pernicious form of this fever must be ascribed, and not the typhoid germ which the authors named had undertaken to discover. The falsity of the supposed parallel etiological support to this view of the case. Thus in the original experiment of Klebs and Tommasi-Crudeli the injection, subcutaneously, of culture-fluids containing their bacillus malariae produced in rabbits a fever of a continued, rather than of a paroxysmal form, and they point out that the Roman fever in man very quickly assumes a continued form. Now we know that rabbits are very susceptible to the various forms of septicemia resulting from the multiplication of septique bacteria of various species in the circulating fluid, or in effused serum in the subcutaneous cellular tissue, etc. And we know, moreover, that all of these forms of septicemia are infectious, and may be transmitted by inoculation from one animal to another. On the other hand, we have no evidence that the rabbit is susceptible to the malarial poison, or that malarial diseases can be transmitted from one individual to another. We have, therefore, no good reason for supposing, with Klebs and Tommassi-Crudeli, that the infectious disease which results from the introduction of their so-called bacillus malariae in the spleen of a rabbit is identical with the paroxysmal fevers known as malarial, after a recent report to the Italian Minister of Agriculture, etc., Tommassi-Crudeli refers to the production of intermittent (?) fever in the lower animals by the subcutaneous injection of the blood of malarial fever patients, and states that he made extensive preparations to continue his experiments in this direction during the year 1882, but he was unable to carry out his intention for the reason that "not a single case of pernicious fever was received during that period into the Roman hospitals" (Quoted from a paper by Dr. C. P. Russel, Medical Record, August 18, 1883, p. 178).

Here, then, we have a confession which makes it evident that the pernicious fever, ascribed to malaria by the author referred to, differs from ordinary malarial fevers—intermittents and remittents—which also prevail in Italy, in the essential particular that it is an infectious disease and may be transmitted to the lower animals, as well as in the fact that it is a continued rather than a paroxysmal fever.

I shall not occupy your time with a more extended review of the arguments and facts which have been advanced in support of the parasitic-germ theory, as explaining the etiology of the malarial fevers, but will say to you that I fully agree with Sir Joseph Fayer, who, in his Croonian Lectures on the Climate and Fevers of India, after giving a summary statement of the various observations during the experiments which have been recorded in favor of this view, remarks as follows:

"The existence of malaria as a particular thing has not yet been demonstrated, and it is still asked if such a thing exist. It may be so; there are circumstances connected with its actions which are difficult to reconcile with a parasitic origin, and, for the present, our attitude with respect to that view should be one of reservation. But who that has followed the progress of pathological investigation during the last quarter of a century would venture to assert that, in such researches as those of Pasteur, Burdon-Sanderson, Lister, Greenfield, Koch, Klebs, Tommassi-Crudeli, and others, we may not find a complete solution of the problem" (British Med. Journal, March 25, 1882, p. 165).

Are we then no nearer the solution of the problem than when Bartlett, and Wood, and Aitken confessed their inability to answer the question, What is malaria? I think we are very much nearer, and that we have good reason to hope that a definite answer will be found in the not remote future. But you will all agree with me that hard and fruitful work have been held from the medical philosophers, is not likely to be disclosed by any speculations or discussion which we may indulge in during the few hours allotted to a consideration of the subject at the present meeting of the Public Health Association, and that our time may be more profitably employed in devising measures for the prevention of disease in the community. We have now come to the point that governmental investigations designed to settle this question, which, both from a sanitary and from an economic point of view, is of such prime importance to the American people.

If Monfalcon was right in asserting that we are much nearer the truth "when we know that we know nothing," than when we mistake erroneous hypothesis for truth, we must admit that a second step is taken in the same direction when we recognize the method by which truth is to be attained.

Not only do we now recognize the experimental method as the only one which is likely to lead us to a definite solution of etiological problems, but we have learned very much during the past decade with reference to the facts, and must admit that living micro-organisms of some kind are concerned in the development of malaria, if we can establish as a fact, that which is very generally believed to be true, viz.: that the evolution of malaria is con-
It is unnecessary to remind you that we have no statistics representing the amount of sickness among the civil population of the United States, and that the sanitary statistics of our decennial census returns relate only to mortality. But for the military population we have, fortunately, very precise data, showing the exact amount of sickness and its nature. As our soldiers are for the most part stationed at military posts which are distributed over the whole length and breadth of the country, they serve as a sanitary test of the diseases due to locality and climate. And, as our statistics for each military post extend over a series of years, we are able to estimate with sufficient accuracy the average amount of sickness and of mortality from diseases of this class, although the number of individuals included in our statistical returns is comparatively small. It must be remembered, however, that our figures relate to selected adult males, and that troops in garrison are often more favorably located as regards sanitary surroundings than is the civil population in the vicinity, especially if this is a scattered rural population. On the other hand, the troops are sometimes subjected to exceptional exposure during their expeditions in pursuit of hostile Indians, etc.; and large portions of the civil population residing in cities are more favorably located as regards exposure to malaria than are our isolated garrisons.

</table>

1 I have not been able to avail myself of the valuable data contained in the two last mentioned publications, for the reason that my paper had already exceeded the length to which I had intended to restrict it before the material in my disposal. In the Report on Hygiene, alone, had received the consideration to which it is fairly entitled.
It is well established that malaria, whatever its real nature may be, is of telluric origin, and that it is evolved more abundantly in rural districts than in cities, where the soil is covered with buildings and pavements.

The data contained in the "Report on Hygiene," published by the Surgeon-General in 1875 (Circular No. 8), embrace a period of four years, from July 1, 1871, to June 30, 1874, inclusive. The figures relating to sickness and mortality are given in tabular form for each year separately, and those relating to temperature and rainfall for each month. These figures relate to two hundred and twelve stations, of which fifty are in the military Division of the Atlantic; forty-eight in the Department of the South and of the Gulf; sixteen in the Department of Texas; twenty-three in the Department of the Missouri; nineteen in the Department of the Platte; twenty-one in the Department of Dakota; and thirty-five in the Military Division of the Pacific. My time and the limits of our annual volume do not permit of an extended discussion of the data relating to all of these military stations, and for my present purpose I have selected a line of posts located upon the Atlantic seaboard, and extending from Eastport, Me., to the extremity of the Florida Peninsula; and a second line of interior posts extending from the head waters of the Mississippi River to Jackson Barracks, La., which is situated on the left bank of the Mississippi, just south of the city of New Orleans.

From the tabular statements given in the report referred to I have estimated the amount of sickness from malarial diseases for each of the selected stations, the annual mean temperature, the annual rainfall, the mean temperature for the months of July, August, and September, and the number of cases of malaria at each of the same stations. These figures are arranged in two tables on page 255, No. 1 including all of the stations on the Atlantic seaboard, and No. 2 including the posts located upon the banks of the Mississippi and Missouri Rivers.

Our army statistics represent the number taken sick during the time specified, and as the same individual may be taken sick a number of times during the year, with intermittent fever, for example, it is evident that the number taken sick may exceed the average strength of command.

Our distinguished American author, Dr. Geo. B. Wood, who has already been quoted as confounding his ignorance as to the real nature of "malaria," nevertheless had very definite views as to the causative which govern its evolution, which he has expressed as follows:

"The circumstances which appear to be essential to the production of miasms are heat, moisture, and vegetable decomposition. The peculiar morbiff effects ascribed to this cause, and by which alone its existence can be recognized, seldom originate at a temperature under 60° F., even though vegetable decomposition may be going on. At 80° they are often very prevalent and are generally checked by the occurrence of frost. A certain continuance of the heat is not less necessary than a certain degree of it. Hence, miasmatic diseases seldom prevail beyond the fifty-eighth degree of latitude; because, though many days in summer may be very hot, the warm season is short. The nearer we approach to the equator the more violent, as a general rule, do they become, implying a greater intensity of the cause" ("Practice of Medicine," vol. i., p. 157).

Evidently if Prof. Wood is right in considering heat, moisture, and vegetable decomposition as essential factors in the production of malaria, the progress of science since his time has made it evident that the nearer we approach to the equator the more violent, as a general rule, do they become, implying a greater intensity of the cause. This would be contrary to universal experience, which is to the effect that malarial districts prevail more extensively in summer than in winter and in warm climates than in northern latitudes. We must, therefore, seek an explanation of this apparent exception to the general rule, and not throw overboard the broad truth that heat is an essential factor in the production of malaria, as some recent writers have done, to accommodate this and other well-settled points. The exceptions must, of course, be due to due weight, and those which occur in our tables prove conclusively that heat is not the only factor, for in this case the amount of sickness should bear a constant ratio to the temperature of a place, and no locality within the established temperature limits would be free from its due proportion of sickness from this cause.

[To be continued.]
COSMETICS.

Their Constituents and General Effects, with a Few Special Cases Other than Saturnism.

By James P. Tuttle, A.M., M.D.,
New York.

It is a reproach to modern civilization that one should find occasion, in this day of enlightenment, to raise his voice against the use of cosmetics.

Aesthetics has done much to cultivate a taste for natural beauty, but it has not yet taught our ladies to appreciate the natural skin above its artificial equipments, except when they see the latter on a rival beauty's face, and the science of chemistry and art of pharmacy have been exhausted to prepare delicate colorings and bright enamels for the complexion. It seems to have been a conception of the ages past that these adornments added to the personal attractions of men as well as women, inflaming passion and calling forth amorous ebullitions in the opposite sex. That it should be held in disrepute will not be questioned, for it was those whose consciences did not falter at whatever means to gain an end—the vicious and vulgar, the harlots and witches—who were the originators of these practices.

Proud Jezabel painted her face to meet the victorious Jehu, and lit the powder charges among the abominations of Ahola and Aholibah, "thou paintedst thine eyes and decked thyself with ornaments to meet strange men."

With such unsavory precedents it would seem that this relic of barbarism would hardly find its way into the better classes of society. But, indeed, it has, and it is fast gaining ground, becoming less obstructive and bold, but more insidious in its effects with every round in the social ladder.

Not only has refinement increased the virulence of cosmetics as a rule, but the more social obligations one has, the more she is compelled to be adorned (?), and have her face pasted, powdered, or painted with these preparations.

Their constant use becomes necessary, because, without exception, those who use them are ashamed to have it known, and the neglect of their artifacts for a single day might expose them to their friends or rivals.

In order to recognize and appreciate the effects of these preparations, it is necessary to acquaint ourselves with their general and possible constituents.

The following are some of the better classes, consisting of very simple preparations, accompanied by much polishing or kneading of the skin, a process, indeed, more healthful than otherwise. Elderflower water, almond oil, and bean-flower water are examples of the preparations used. Says Samuel Johnson: "I was never allowed to sleep till I passed through the cosmestic discipline, part of which was regular lustration performed with bean-flower water and may-dews."

But this practice did not cover up deformities or remove defects, as freckles, moles, or tan, and stronger preparations began to be sought. Oil of cashew gained a favorable reputation in the removal of sunburn and freckles, but the pain following its use brought it into disrepute. After this the use of corrosive sublimate came into vogue, and rose- or elder-water was beaten down with bitter almonds, and this drug added in varying proportions. Then came the face powders to cover up deformities, in which are incorporated bismuth, calcium, zinc, lead, French chalk, etc. These preparations are largely sold to-day. In 1870 Dr. W. E. Chandler published in the Central Board of Health on "Dangerous Cosmetics." He there showed that, with one exception, sixteen hair tonics which he was able to examine contained carbonate or other compound of lead. The exception. "Hoyt's Hiawatha Hair Restorative," contained nitrate of silver. Sulphur was incorporated with the lead to produce the black sulphide.

After analyzing a number of "lotions," containing, with one exception, "no injurious metal," "enamels" containing zinc and lead generally, and "powders" composed of calcium, French chalk, magnesium, and bismuth, he concludes:

1. With few exceptions, hair tonics, washes, and restoratives contain lead in considerable quantities; that they owe their action to this metal, and are highly dangerous to the health of the person using them.

2. With a single exception, Perry's Moot Lotion, the liquids for the skin are free from lead or other injurious metals.

3. That the enamels are composed of carbonate of lime, oxide of zinc, or carbonate of lead, suspended in waters. The first two classes of enamels are comparatively harmless—as harmless as any other white dirt when plastered over the skin to close its pores and prevent its healthy action. On the other hand, the enamels composed of carbonate of lead are highly dangerous, and their use is certain to produce disastrous results to those who patronize them.

4. The white powders for the skin are harmless, except in so far as their use may interfere with the healthy action of the skin.

He has stated these conclusions in full on account of my respect for their author, and because they come partly at the truth; nevertheless, I shall have to differ materially from the latter three. Carrying the analyses further, I have derived the following:

It is a popular misconception, into which Dr. Chandler has almost fallen, that only those preparations containing lead are deleterious in their constitutional effects. The fact that mercury is contained in any of these preparations will be a surprise to many of their patrons, and convincing proof that "warranted free from lead" does not make them harmless.

The similar behavior of lead, mercury, zinc, and bismuth with the alkali metals found in the blood would in the beginning suggest an analogy in their physiological effects.

That this expectation has been at least in part met, is exemplified in the differential diagnosis of chronic lead and mercuric poisoning. The acute toxic effects of these drugs are no less similar, and I am persuaded that zinc, and possibly bismuth, may have produced the same general effects.

The assumption that all dangerous cosmetics contain lead is more general than one would suppose, and due to two facts, viz.: formerly the majority did contain it; and secondly, many cases of poisoning closely resembling falling plumbism have been attributed by the use of these preparations. But the similarity of effects produced by other drugs invalidates conclusions on these grounds, and, moreover, preparations which it is positively asserted have produced acute and chronic plumbism, contain no lead whatever, but salts of zinc, as we shall see further on. Workers in zinc have been fre-
ently attacked with so-called lead-poisoning, said to be due to the use of mercury in combination with the zinc, and it is claimed by some that they are even more subject to general progressive muscular atrophy than workers in lead. Furthermore, they are equally subject to constipation, colic, and hemorrhages from the lungs. 1 Says Dr. Bartholow, 2 "All the salts of zinc, when long continued, may produce a train of symptoms not unlike those of lead, viz.: constipation, pallor, loss of strength, constipation, colic, muscular weakness and trembling, paralysis, etc. The oxide in large doses, and continued for a long time, has produced a fetid breath, wasting, gastro-intestinal catarrh, and feeble-mindedness. 3 Ringer bears similar testimony as to the effects of this metal. 4 Oxide of zinc, used in painting, has produced colic similar to that of lead. 5 To argue controversy on this on the ground of frequent indiscriminate use of the official ung. zinci oxidii would be of no avail, as this could be offset by the similar and harmless use of pure carbonate of lead in burns, scalds, and wounds.

That the substances are insoluble offers nothing to the contrary of their constitutional effects, for it is well known that they will dissolve, find their way into the lymphatic, and thence into the general system, more readily than watery solutions. 4 Of the effects of the local use of mercury, it is unnecessary for me to speak. For its disastrous results one need only consult the nearest work on therapeutics or toxicology. I have seen, in one case, severe salivation following the local use of this metal. I have seen the grains of calomel, and torturing cramps and nausea from a weak solution of the corrosive chloride for pediatric capitis. Numerous instances of necrosis, gangrene, and death from equally small doses are on record. 4 Bismuth is an astringent metal, and besides its effects in stopping up the pores and preventing the healthy action of the skin, it is found in the indications of the organic cosmetic, to produce "clamminess, nausea, and spasmus," differing in degree only from those of lead, mercury, and zinc. 5 Notwithstanding such facts, all of these metals are freely used in the cosmetic preparations for sale in every pharmacy, and there is no law to protect the public against them. Lately I have come in contact with five cases of poisoning by cosmetics, confirming the opinion hereinbefore set forth.

Mrs. — , a lady in good society, came to my office to ask if it were possible to be poisoned by cosmetics. I replied "Most certainly," and she related the following: A few days before, she had begun the use of a new cosmetic, recommended by two of her friends. She applied it morning and evening, and on the second evening, about an hour after the preparation had been on, she noticed a metallic taste in the mouth, and was seized with nausea and "cramps in the stomach." The cramps were severe, but supposeing they were due to simple indigestion, home remedies were used to make them tolerable. On the following day small vesicles appeared at the corners of the month. The "cramps" continued, and in the evening, after another application of the lotion, they increased and the nausea returned. There had been no diarhœa, but rather the opposite. On the day after this I saw her, when the cramps had greatly subsided, but the herpial eruption remained about the corners of the mouth; there was not much swelling or tenderness of the gums, but rather increased salivary secretion and constant metallic taste in the mouth. On discontinuance of the use of the preparation, the symptoms disappeared and have not since returned.

Case II., a friend of the former patient, who had been using the same cosmetic, is similar in every respect to the last with the exception of severer cramps perhaps.

Case III., Miss — , has used the same preparation for some months. During this time she has been confined to her room several times by "cramp colic," nausea, etc. She has a constant metallic taste in the mouth, and lately has not only lost flesh, but also power in her right arm and leg, and has severe aching pains in her limbs.

I obtained the remaining part of the preparation which my first patient had been using, and on chemical analysis found it to contain almost nothing save pure chloride of mercury and water. To prevent error an unopened bottle of the same was procured from a reputable pharmacist, an examination of which exactly coincided with the first. A little sugar, supposedly to give lustre to the enamel, is inserted. And yet this preparation, "Gouraud's Oriental Cream," is labeled "the most elegant and delicate preparation for the skin ever invented." Comment is unnecessary here—further than to add, an average application contains from four to ten grains of the drug.

Case IV., Miss — , is a young lady who has been using "Laird's Bloom of Youth" for a long time as a cosmetic. Several eruptions had occurred, constipation, weakness, atrophy of the muscular system (and diminished reflex activity?). Numerous instances of injury from this preparation have been related, and some have been published. 1 An examination of the preparation shows it to contain no lead, but oxide of zinc and a small amount of calcium carbonate. A report by Dr. V., Hospital was reported in the daily papers of this city as one of "lead-poisoning" from cosmetics. Dr. Herold, the physician in charge, was kind enough to tell me that there were some of the symptoms of saturnism wanting, and that the preparation she had been using was "grease paint." I obtained a "stick" of this, and on examination found it contained oil of bitter almonds, a saturated solution of tallow. This and similar preparations are largely used by theatrical people, under the impression that they are entirely harmless; yet I doubt not much of the colic and malaise, so abundant in this class, is produced by them.

Of the powders containing only calcium, magnesia, and French chalk, I am unable to affirm any constitutional effects beyond those due to stopping the pores of the skin; but they are certainly very prejudicial to the healthful action of that organ, and many a fair complexion has been ruined by their use.

Bismuth is becoming less used on account of its changing its color in the presence of certain gases, and its expensiveness. Here let me say the manufacturing of cosmetics is a most profitable business. As early as the publication of the Spectator, No. 33, it was said, "I have known a physician of learning and sense, after eight years' study in the university and a course of travel into most of the countries of Europe, owe the last raisings of his fortune to a cosmetic wash," and if I mistake not, some in our present day could see their financial fortunes rise by peddling cosmetics instead of pills.

I have already said enough to anticipate what I shall here add as conclusions from this study.

First.—All preparations which can clog the pores or irritate the skin are prejudicial to the health and beauty of that organ.

Second.—Lead, mercury, zinc, and bismuth, may be absorbed into the system from their application to the skin, produce the same general constitutional disturbances, differing mostly in degree, and are harmful in their respective order.

Third.—Dyspepsia, nausea, constipation or diarrhœa, colic, emaciation, tremors, paralysis, and weakness, may be brought on by the use of these preparations.

THE MEDICAL RECORD.

other of these classes, produce local or systemic injury, and are therefore unfit and dangerous to use.

Fifth.—A law should be enacted requiring all manufacturers to print in full all articles contained in their preparations, and at the same time prohibiting the sale of those containing the more dangerous metals.

It is futile for manufacturers to sign themselves chemists and M.D.'s, and claim that these are the drugs used by physicians for skin complaints.

An engine with the hand of a skilful engineer on the throttle is a useful thing, but let an ignorant passenger sit in his place, and it will dash onward to destruction with its precious freight—so, also, a drug which the physicians we should learn the best ways to perfect the human skin, and yet we should fail to do our duty to society did we not use every means in our power to check these vicious and dangerous practices.

SOME OBSERVATIONS ON THE SALINE CAT-HARTIC WATERS OF SARATOGA,

WITH THE INDICATIONS AND CONTRA-INDICATIONS FOR THEIR USE.

BY W. G. ALLING, M.D.,

NEW HAVEN, CONNECTICUT.

MINERAL spring waters have been known and acknowledged as efficient remedies in the treatment of disease from the earliest ages. So popular is the confidence reposed in their healing power that not a spring of any value is discovered which does not gain, at least, a local reputation. Mineral waters ranked high among the ancient remedies used for the cure of disease, and the universal favor in which they are now held by all civilized people sufficiently demonstrates that their reputation is thoroughly established. With the modern nations of civilized Europe mineral waters have always been held in high estimation. Karlsbad Spring has been known and patronized as a health resort for more than five hundred years, and has a world-wide fame. In 1880 there were three hundred and ninety-four Americans recorded as being under medical treatment at Karlsbad Springs.

The most eminent English and European physicians prescribe a course of mineral water for their patients very frequently, while the physicians of this country do so very rarely. My observation leads me to believe that a more frequent resort to this class of therapeutic agents by the profession would prove of great benefit in the treatment of a large class of chronic diseases.

That eminent French physician, Trouseau, devoted much time to writing on this subject, and throughout his clinical work, as well as the able work of Prof. Niemeyer, mineral waters are assigned an important place in the treatment of many chronic diseases.

Although mineral waters have been favorite remedial agents with the enlightened nations of the earth for many centuries, it was not until 1670 that they were first fully analyzed. A correct chemical analysis of mineral waters is always of great importance, this only enabling the physician to direct general views relative to the nature and powers of the waters. It must be conceded that an analysis, however correct, will not always indicate the disease to which the water is applicable; still, in the majority of instances, it forms an exceedingly valuable guide and one which cannot be overlooked.

The number of reputable mineral springs of the world is very large, the springs of Europe numbering about four thousand three thousand and fifty, France alone containing nearly seven hundred. But in no other country, probably, do mineral waters abound in greater variety than in the United States, the number of well-known springs being about six hundred. It is a subject of sin-

cere regret that their nature, applicability, and proper methods of administration should have been so little studied by physicians at large.

Of the large number of mineral springs in this country, undoubtedly those of Saratoga are the most famous, some of them having a world-wide reputation, as the old "Congress Spring," which was discovered in 1792. This, without doubt, is one of the best and safest saline cathartic waters ever discovered either in this country or Europe. Saratoga owes its wonderful growth and popularity largely to the recognized medicinal merit of Congress Spring water. The advantageous combinations of its salts, and its almost entire freedom from iron, should give it the well-merited preference it has attained as a cathartic water. Its action is prompt and pleasant, without producing debility or intestinal irritation, and it certainly is strong enough for daily use, but not so strong as to produce a reaction.

Professor Chandler, who has analyzed nearly all of the spring waters of Saratoga, including Congress Spring, says: "In submitting my analysis, I take pleasure in saying that a comparison of the same with the analysis by Dr. Steel in 1832 proves that the Congress water still retains its original strength, and all the virtues which establish its well-merited reputation. Its superior excellence is due to the fact that it contains, in the most desirable proportions, those well-beloved medicinal effects, its agreeable flavor and satisfactory medicinal effects, neither holding them in excess nor lacking any constituent to be desired in this class of waters."

Congress Spring water contains much the largest amount of bromine of any spring in Saratoga, and it also contains a considerable amount of iodine, placing it in the class of iodo-bromuretted waters, of which very few are known.

Besides the Congress there are five other springs in Saratoga classed as cathartic or saline laxative waters.

The Excelsior and Union Springs were discovered in 1814, but were not tubed till 1859 and 1868, respectively. The water from these springs will be found a mild but pleasant laxative. My observations of their effects lead me to believe that they will be found more useful where an alterative and diuretic effect is indicated than as a cathartic.

Hathorn Spring was accidentally discovered in 1868, while digging for the foundation of a building, and rapidly sprang into favor, probably owing more to accidental circumtances than to any well-beloved medicinal qualities; in fact, before its true chemical composition and medicinal action was known.

Hathorn Spring is the strongest natural spring yet discovered in this country. The strongest mineral waters, like the strongest medicines, have their sphere of usefulness in the treatment of certain diseases, and often prove of immediate benefit; but that they are capable of doing irreparable injury is well known by all physicians who are familiar with their action. My own observations of the effects of Hathorn Spring water have been that many cases of severe stomach and intestinal irritations are caused by any freedom in its use.

Serious treatment by an active, complicated agent, such as this water is, demands constant medical supervision by an experienced physician, who thoroughly understands its present chemical composition. Since this water was analyzed by Professor Chandler, in 1869, the spring has been re-dug and re-tubed, changing its depth and the lower end of tube several feet in a lateral direction. Recent tests seem to show quite a change in its chemical composition, demand the exact volume of the water which it is now shown to contain. By published analysis this spring contains much the largest amount of iron of any of the springs classed as cathartic waters. This fact seriously challenges its safety when prescribed or used.

1 Saratoga Mineral Waters, by Dr. W. O. Stillman.
2 Johnson's Encyclopedia.
freely or indiscriminately, as it so often has been. An eminent physician says, "One grain of iron in mineral water, in combination with carbonic acid gas, is more potent than iron. Some persons cannot take it in any form, not even a single dose of a weak ferruginous water. The digestive organs of some patients are easily upset by it."

When iron is present in quantities of a grain or more to the gallon the spring is called a chalybeate. This spring, therefore, should be considered and classed as a saline, chalybeate water, and should only be prescribed for those diseases to which this class of waters is applicable.

The Geyser and Champion Spouting Springs are located about one and one-half mile south of Congress Spring, and were brought into existence and notice during 1870 and 1871, by boring through solid rock. The Geyser springs a fine jet of hot water thirty feet in diameter, one hundred and thirty-two feet in depth. The Champion has a tube two inches in diameter and is three hundred feet deep. So great is the evolution of carbonic acid gas that the water spouts through a two-inch nozzle to the height of eighty or one hundred feet.

The waters from these springs resemble each other very closely in chemical composition, the Champion being the stronger of the two. They are, therefore, therapeutically indicated in essentially the same class of diseases. The mineral impregnation of these waters is very great, so much so, that rapid incrustation of lime occurs on whatever is placed within reach of their spray.

In all of the Saratoga waters the principal constituents are chloride of the alkaline carbonates, and carbonic acid gas. Chloride of soda is one of the most important elements in all organic substances. It is contained in large quantities in all tissues and liquids of the human system. When introduced into the stomach it excites the secretions of gastric juice and favors peristaltic action, and when taken in considerable quantity is a most efficacious remedy for biliousness. It is well known that a considerable quantity of chloride of soda taken into the circulation increases the excretion of nitrogenous products, accelerating the transformation of tissue.

In speaking of the uses of the saline cathartic waters of Saratoga, I shall confine my remarks to a few observations (of a general character only) on their medicinal application in the treatment of disease. Special directions can only be given with safety to the patient from a careful investigation of the particular symptoms and character of each individual case. The necessity and benefit to be derived from an occasional cathartic to most persons few will deny. The most satisfactory results constantly follow this cleansing process. The advantages in such purgation in aiding the operations of the intellectual and imaginative faculties, is perhaps not known or admitted; yet we have no less considerable authority than that of Dryden and of Byron on this point. Dryden says: "When I have a grand design I ever take physic; for when you would have pure swiftness of thought, and fiery flights of fancy, you must have a care of the penive part, in fine you must purge the belly." And Lord Byron observes: "The thing that gives me the highest spirits (it seems absurd, but true) is a dose of salts; but one can't take them like champagne." And we have far more ancient testimony to the same effect. We are told that Carneades, one of the most famous disputants of antiquity, was accustomed to take a copious dose of white heliotrope, a great appetizant, as a preparation to refute the dogmas of the Stoics.1

Saline cathartic or laxative waters increase the appetite and improve the digestion. After absorption, we get increased activity of the secreting organs, by which these salts are eliminated from the blood, as well as increased activity in the gastro-intestinal glands, by which the digestive fluids are secreted, and in this way they act as stimulants to digestion, the peristaltic action of the stomach is accelerated and its contents are more rapidly removed.

The strong, parah, saline waters produce watery salivary ejections, and if long continued an irritation and even inflammation of the intestinal canal. This is a point to be borne in mind, and it should not be overlooked in prescribing this class of waters. Chloride of sodium waters above a medium strength are irritating to certain constitutions, and capable of exciting gastric cachexia.

In many diseases there exists a state of the intestinal canal, giving rise to the retention of its contents, which is not to be obviated by the occasional administration of an ordinary cathartic. In such cases the drinking of a large quantity of carbonized mineral water leads to a sort of general flushing out of the sewers of the system and is very serviceable, and is the more necessary the more difficult, and is nearly necessary to health and nutrition. It helps us to get rid of the old, the worn out, or half worn parts of us, and it helps us to build up a new and better man. Frequent and copious dejections are not desirable, as this would eliminate the greater portion of the salts, and thereby frustrate their absorption; one or two free daily evacuations are sufficient for patients under treatment. However, it seems to be the general opinion of mineral water drinkers that a cure can only be effected by much purging. It is always well to remind patients that the advantages of having recourse to these waters is often felt more after than during active treatment.

The saline cathartic waters of Saratoga have proved of great value, and are therapeutically indicated when it is found necessary to increase the activity of the stomach and intestines, to improve digestion and assimilation, and to promote absorption. They are therefore applicable in a long list of maladies arising from congestion or obstruction in the abdominal organs.

In constipation and in hemorrhoids occurring as a result of constipation these waters have achieved some of their greatest results.

In abdominal plethora they afford prompt and grateful relief. With students and professional men of sedentary habits their action is peculiarly happy, relieving a variety of nervous phenomena, promoting sleep and tranquillity.

Jaundice, when due to catarrh of the biliary duct or obstruction from biliary calculi, engorged conditions of the liver, when not occasioned by organic disease, are especially amenable to their use. In enlarged spleen, produced by intermittent fever, and also in chronic malarial diseases these waters may be employed with great confidence in their ultimate success.

These waters have for many years enjoyed an immense reputation in the treatment of scrofula and all affections commonly associated with it, and the best results have undoubtedly often been attained. Dr. Steel says: "Experience has abundantly sanctioned the belief of their utility in this disease, and since iodine was discovered in these waters they are prescribed in these affections with considerable success." And Lord Byron observes: "The importance of this agent is calculated to impress."

Congress water contains much the largest amount of bromide of sodium and also iodide of sodium of any spring in Saratoga, making it a valuable water in the treatment of this class of disease. In chronic eczema this class of waters has accomplished many cures. Excellent results have followed their use in herpes, acne, and psoriasis.

In chronic congestion of the brain or spinal cord, or their meninges, attended with constipation, the simple

1 Johnson's Cyclopaedia.
2 Diodot's Curiosities of Literature.
cathartic waters are often of immediate benefit. They relieve blood-pressure by draining off the superabundant serum of the blood, without sacrificing its more vital elements or exerting any irritating influence. But in these conditions those waters containing any appreciable amount of iron are to be strictly forbidden.

When it is desirable to act freely on the bowels, when constipation is obstinate and habitual, or there is fullness of blood, and depletion is needful, much time may be saved by beginning treatment with a mercurial or saline cathartic, sufficient to move the bowels freely.

The best time of the year to carry out an effective course of mineral water must be decided by circumstances. It is easy to see that it may be advantageously employed at all seasons of the year. The old idea that they were not admissible in winter has been entirely abandoned.

Many diseases do not admit of delay, and for this purpose the bottled waters are quite as effective as when fresh from the spring. The best time of the day for drinking is in the early morning when the body is refreshed by rest, the mind tranquil, the stomach empty, and the quantity of fluid in the system being much diminished the water is more easily absorbed. At least a quarter of an hour should elapse between each glass, and a full half hour between the last glass and breakfast. Any persons using mineral waters should dress warmly, the digestive organs being more easily warmed in cases where the digestive organs are seriously implicated, the water should be taken warm, and naught gentle exercise in the open air should be taken.

Patients are often sent to the springs with positive directions from their physicians to drink so many glasses of a certain spring water per day, whether it agrees with them or not, when in all probability the whole be the most prejudicial to which they could resort. Used in this rap-hazard manner, it is not strange, that many leave the springs not benefited, or in a worse condition than when they arrived.

A more accurate knowledge of the component parts of these waters will do much to prevent the mistakes and injury so often done.

It is a subject of daily observation during the drinking season in Saratoga to see numerous individuals using mineral waters that are not adapted to their case, and to see those to whose cases they are adapted using them so improperly as to entirely prevent the good they would otherwise probably administer.

In France, Germany, and England the advice of a competent physician, who is well acquainted with the nature and peculiarities of the waters, is considered of so much importance that at many of the springs persons are actually forbidden to take the water without such advice.

A CASE OF SYMPATHETIC SEROUS IRIIS, WITH REMARKS.

BY DAVID WEBSTER, M.D.,
PROFESSOR OF OPHTHALMOLOGY IN THE NEW YORK POLYCLINIC.

SEROUS iritis is a comparatively rare form of sympathetic inflammation. During about fifteen years of ophthalmic practice, in which many thousands of patients with diseases of the eye have come under my observation, I have never seen, to the best of my recollection, but a single uncomplicated case, the one which is here with reported.

Fortunately, of late years, the cases of sympathetic inflammation of all kinds that come under the care of the ophthalmologist are comparatively few. The offending eye is now generally enucleated while the fellow eye is in a state of sympathetic irritation only, and before true sympathetic inflammation has set in. It is true that cases have been reported in which sympathetic inflammation has attacked the remaining eye after enucleation of the lost or injured eye, but such cases are so uncommon that very few ophthalmologists have ever met with them.

There can be no doubt that the proper time to enucleate is during the stage of sympathetic irritation. But we do not always have a well-marked stage of sympathetic irritation. True sympathetic inflammation may be ushered in without any premonitory symptoms. What shall we do in such cases? My answer is, if the eye causing the sympathetic inflammation is hopelessly blind, enucleation should be resorted to without delay. However, whenever any of the other eye will be saved if the one causing the sympathetic is enucleated within a day or two after the first symptoms of sympathetic inflammation have shown themselves, no matter what variety of sympathetic inflammation we have to deal with. My own experience is limited to two cases. The first was a case of sympathetic keratitis, with adhesions, and was published in the Archives of Ophthalmology. The eye recovered rapidly after the enucleation of its fellow, in which was found a piece of gun-cap, and still has vision 40/40. It was at the last examination apparently perfect in all respects. The second case is the subject of this paper.

I do not like the idea advocated by some, of enucleating an eye which is liable to produce sympathetic trouble, even although it be hopelessly blind. A blind eye often looks better than an artificial eye, and subjects the wearer to much less expense and inconvenience. It is a matter of common observation that if the eye of a child is enucleated the corresponding side of the face is subject to an arrest of development in marked degree. In my cases progressive contraction of the orbital cavity occurs, so that the patient is compelled to change the artificial eye for a smaller one until, finally, not even the smallest one can be worn. In other cases there is an obstinate conjunctivitis of the cavity, with a slimy mucous secretion, or a constant overflow of tears, resisting all methods of treatment, and subjecting the patient to great annoyance.

I would, as a rule, then, not enucleate, for fear that sympathetic irritation or sympathetic inflammation might occur, but would warn the patient of such a possibility, and would try to impress upon his mind the necessity of consulting a competent surgeon without delay, if the few days or weeks should become weeks or months.

In my cases progressive contraction of the orbital cavity occurs, so that the patient is compelled to change the artificial eye for a smaller one until, finally, not even the smallest one can be worn. In other cases there is an obstinate conjunctivitis of the cavity, with a slimy mucous secretion, or a constant overflow of tears, resisting all methods of treatment, and subjecting the patient to great annoyance.

I am in favor of enucleating a totally blind and useless eye, at the earliest possible moment, for sympathetic inflammation of every kind—always supposing that the eye sympathetically inflamed has not been already lost before the case comes under observation. I am aware that, in this opinion, I am not in accord with Mauthner, of Vienna, and many others. Mauthner's "creed" is as follows: "Enucleation may be performed as a preventive; it must be performed in the stage of irritation; it must not be performed in serous iritis and plastic iritis; it may be performed in plastic irido-cyclitis, provided the eye causing sympathetic inflammation is totally blind, but not in states of violent irritation."

As I have stated above, my own experience has shown that it may be performed, and with the best results, in both serous and plastic iritis, despite the authority of Mauthner, Samelsohn, and others. I would not be willing to assume the responsibility of advising against enucleation in sympathetic iritis, except in cases where the existence of a fellow eye was a fair patient of the recovery of the sight of the vision in the eye causing the sympathetic inflammation.

It is remarkable that high authorities differ as to the diagnosis of serous iritis. Adolf Alt, who wrote the best book that ever was written on the pathology of the eye, says ("Lectures on the Human Eye"): "Serous iritis does not seem to materially alter the anterior endothelial coat. The uveal layer, however, is mostly altered in such
a way that its elements become remarkably glutinous, and the posterior surface of the iris thus becomes adherent to the anterior capsule of the crystalline lens.

If the pupillary edge of the iris has thus become glued to the anterior lens capsule, it often happens that the exudation in the posterior chamber pressures the periphery of the iris forward into the anterior chamber, and thus causes the iris to become what has been styled "crater-shaped." Mauthner, on the other hand, says ("Sympathetic Diseases of the Eye," Webster and Spalding's translation, p. 75): "It should, moreover, be distinctly borne in mind that we are not directly to diagnosticate serous iritis on account of the presence of nodules of exudation, but to look about for other alterations in the eye."

If, for instance, a case of sympathetic serous iritis would here agree with Mauthner, and would call Alt's case, with "crater-shaped" iris, one of plastic iritis.

Wells says ("Diseases of the Eye," fourth American edition, p. 335) that sympathetic serous iritis is "much less common, and much less dangerous than sympathetic iritis-cyclitis." He adds: "It is true we should hope and expect to prevent its 'passing over into the latter' by the prompt enucleation of the offending eye."

The case I have to report is as follows:

April 10, 1883.—Maggie O'G—six years of age, while playing school with a little girl on her father's front stoop, was struck in the left eye by a fragment of a glass bottle. She was taken immediately to the family physician, Dr. George L. Simpson, who said that he feared the eye was lost, applied a bandage, and instructed the parents to bring the child to me without delay. I saw her about an hour after the injury occurred. She vomited from the shock of the injury both on the way and while in the office. I found the eyeball in a state of collapse, apparently less than two-thirds its normal size, its contents mixed with blood, and across its anterior surface, extending through the whole width of the cornea and through the ciliary region on one side, an irregular wound through which a large mass of bloody vitreous was protruding.

I gave the father an unfavorable prognosis, but concluded to try to save the eye, with any expectation of vision. A retentive flannel bandage with absorbent cotton was applied, and a little parerogenic was ordered to be taken if necessary to relieve the pain.

The child was under my observation, from this time on, at the New York Polyclinic, where she was seen three times a week, Dr. Simpson attending to her himself on the alternate days. The eye was carefully washed, daily, and the bandage reapplied. There was very little pain, and almost no apparent inflammatory reaction. The eyeball rapidly plummed up, and soon attained a normal degree of tension. The protruding vitreous gradually disappeared as the wound healed, and the blood was absorbed from the anterior chamber. There was anterior synechiae, and an opaque mass in the misshapen pupil—which made examination of the interior of the eye impossible. At one time the child seemed to see a little with the injured eye, counting fingers near at hand with uncertainty. From this time there was considerable photophobia, and about three weeks after the injury it was observed that the child involuntarily kept looking to the left. After this time the injured eye became more inflamed and irritable, and it became more difficult to examine it.

On May 10th, exactly one month after the injury, slight irritation of the right eye was observed. The next day, as there was the least blush of redness of the sclera,
TWO CASES OF EMPYEMA.

BY F. H. DILLINGHAM, M.D.

LATE HOUSE PHYSICIAN OF ST. FRANCIS HOSPITAL, N. Y.

There being so much discussion by the medical profession on the subject of empyema, I have thought that the history of the following cases, which occurred during my service in the hospital, might be of interest.

Case 1. Emphyema; free incision; recovery. — Patrick C____, twenty-six years of age, U. S., single, bricklayer, was admitted to the medical ward of St. Francis Hospital (Dr. John H. Ripley, visiting physician) May 6, 1881. Parents living, also three brothers and two sisters. One brother dead. No evidence of syphilis. Has suffered from chronic rheumatism in right knee and thigh for the past eighteen months; otherwise has been perfectly well until May 3d, when on waking in the morning he was taken with nausea, vomiting, and "a catching in the right side below nipple." Has pain in coughing, and feels better when he is lying on his right side. Has considerable dyspnoea, but has had no chill. On admission, patient was very weak, and breathing with great difficulty. Examination showed the apex-beat under the left nipple; fatness both anteriorly and posteriorly over the entire right lung, and absence of vocal fremitus and respiratory murmur, except at apex, where there was bronchial breathing. Over the left lung there was exagerrated breathing. Liver dulness 3 inches below costal margin. Temperature, 104°; pulse, 120. Urine examined with negative results. Quinine and brandy ordered.

May 7th.—Examined by Dr. Ripley, who ordered aspiration, which was done, but no fluid found. Temperature A.M., 102°; P.M., 104°.

May 8th.—Patient about the same. Temperature in the morning, 103°; evening, 105°; pulse, 118.

May 9th.—A very long hypodermic needle was introduced four times, in different places, by Dr. Ripley, but no fluid obtained. Physical signs the same as on admission. Temperature A.M., 103°; P.M., 104°; pulse, 114.

May 11th.—Hypodermic needle introduced twice, with the same result as before. Temperature A.M., 103°; P.M., 104°; pulse, 120.

May 15th.—Hypodermic needle again introduced, but no fluid found. The temperature has been about 101° mornings, and 104° evenings.

May 19th.—No change in physical signs or temperature range. Patient takes very little nourishment. Hypodermic needle ordered to no purpose.

May 20th.—Patient has been gradually growing weaker. Tr. ferri acetatis, gtt. xv., t.i.d., ordered.

May 25th.—The last three days has been growing a little stronger. Hypodermic needle introduced, and a little clear serum drawn off. About the same range in temperature.

June 5th.—Temperature has varied between 100° and 104°. Decided to aspirate, which was done, after finding fluid with the hypodermic needle. Only succeeded, however, in drawing off about two ounces, containing a trace of pus.

June 6th.—No change in the physical signs. Patient has been gaining very slowly. Temperature A.M., 100°; P.M., 105°; pulse, 104.

June 10th.—Has been very slight reduction in temperature. Hypodermic needle inserted and a little fluid found, containing a larger percentage of pus than before.

June 15th.—The only place where fluid could be found was on the right side, anteriorly, between the fifth and sixth ribs, nearly under the nipple, where I aspirated him, and drew off about a pint of slightly purulent fluid. Temperature has ranged between 100° and 103°.

June 17th.—Blistered anteriorly on the right side, without much beneficial result.

June 20th.—Very good breathing posteriorly over right lung, nearly to angle of scapula. Liver and spleen slightly enlarged.

June 24th.—Commenced to sit up a little. Hypodermic used and the fluid drawn off was more markedly purulent.

July 4th.—Patient has been growing worse the last few days. Hypodermic needle introduced several times, but no fluid found. The temperature has ranged between 100° and 104°; pulse, about 100.

July 6th.—In the patient has been falling fast, it was decided to open the pleural cavity by free incision, which Dr. Ripley kindly intrusted to me. No anaesthetic was used. The needle was introduced several times with no success, except in the fifth intercostal space, in the mammary line, where pus was found. I then made a free incision at this point, with a sharp-pointed bistoury, and, including two directors, withdrew the knife, when sixty ounces of pus were slowly and intermittently discharged. During the process of drawing off the fluid, the flow would suddenly cease, when, after an explosive cough, a large caseous mass would be expelled through the wound, and the discharge begin again. This was repeated several times.

The patient was very weak, and brawny and fibrinous, and contained large cheesy masses. The cavity was washed out with warm water, and a drainage-tube inserted, the wound covered with oakum supported by a bandage, the patient feeling very much relieved.

July 7th.—Has passed a good night, and feels much better. Dressing removed, and the cavity washed; cold water being used. Temperature A.M., 98°; P.M., 104°; pulse, 96.

July 14th.—Patient has had a little diarrhoea the last four days, which has now ceased. Temperature varies between 98° and 101°.

July 15th.—Is feeling much stronger, appetite good, and sleeps well. Discharge diminishing.

July 19th.—Patient sitting up; there has been a great improvement in every respect.

August 23d.—He is up and around the wards all day. Temperature has ranged between 100° and 103°, in spite of remedial measures. On account of this, the desirability of making a counter opening was discussed, but at the patient's request, and as he was growing no worse, it was deferred. The drainage-tube was changed for a shorter one.

August 25th.—Discharge has begun to become less, and a little clearer. Temperature slightly diminished.

October 4th.—Patient is feeling very well, and able to do a little light work in the hospital.

November 10th.—Has been gradually gaining. Very little discharge.

December 1st.—A smaller and shorter drainage-tube inserted.

December 10th.—No discharge, and the water returns perfectly clear. Temperature has ranged from normal to 103°, but after this did not go above 100°.

December 20th.—Patient has rapidly improved. Temperature normal. No discharge, and only a few ounces of water can be forced in the cavity. Drainage tube removed, but oakum used to keep the opening from closing.

January 10th.—Patient's appetite is good, and he is getting fat and strong. He was advised to leave the hospital, as he would do much better outside, but as he had no home, he preferred to remain and perform the duties of surgical orderly.

He served as orderly for some months, and when he left the hospital was strong and well. The wound was nearly closed, there being no discharge. It was retarded to a great extent by his confinement and work in the surgical wards.

Pulsting empyema following typhoid pneumonia; free incision; temporary relief. — Henry F____, twenty-six years of age, U. S., married, cigar maker, admitted to the medical ward of St. Francis Hospital (Dr. John H. Ripley visiting physician) April 6, 1881. His father was killed in the war, and his mother died during menopause. Two brothers living and
THE MEDICAL RECORD.

[March 8, 1884.

well. No evidence of syphilis. He had always been healthy, until about ten months before his admission, when he began to be troubled with a cough, with yellowish spuets, and slight night sweats. He had no dyspnoea or pain, but lost considerable flesh and strength. During the summer, his cough was so severe that it often caused emesis.

In December, 1880, during a violent attack of coughing, he was seized with a sharp pain in his left chest, followed by great dyspnoea, cold sweats, blue extremities, etc. He improved a little, and then remained about the same until the first of March, when he found himself growing weaker and the dyspnoea increasing.

For the four weeks previous to admission, he had not had any chills or night sweats, nor had his cough been so distressing.

On examination, patient was very weak, and his dyspnoea so great that he could not lie down or sleep. Has considerable cough and no appetite. Face and neck cyanotic, and slight increase in size of abdomen, especially on the left side. Apex-beat nearly at right nipple. Temperature 101°F; pulse, 120.

On physical examination of the chest, flatness on percussion could be noted over the lower three-fourths of the left lung; above this it was tympanitic, the level of flatness varying with change of position. Over the lower three-fourths there was absence of respiratory sound; and above amorphous respiration and position tinkles. Succession was well marked. Over the right side there was exaggerated breathing. The urine was examined with negative results. Cough mixture and plenty of stimulants ordered.

The next day (April 7th) I aspirated him and drew off forty ounces of pus. During the operation he showed signs of syncope, and it was necessary to give him hypnotics of brandy. An hour after he felt very much relieved; his dyspnoea was greatly lessened, but his pulse was very weak. Temperature A.M., 100°F; P.M., 99°F.

April 8th. Has been able to lie down and sleep a little during the night; feels stronger, but his cough is still troublesome. Temperature A.M., 99°F; P.M., 100°F. Tonics ordered.

April 9th. Had a good night’s rest. Commences to eat a little, and is slowly improving. Temperature A.M., 99°F; P.M., 100°F. Pulse, 100.

April 14th. Dyspnoea is increasing; aside from this, feels pretty well.

April 15th. Aspirated, and seventy ounces of pus drawn off; but he became so weak that it was necessary to stop before the cavity was emptied.

April 16th. Feels better than he has for two months, appetite very good. Temperature has not been above 99°F.

April 23rd. Has been doing nicely until to-day, when he began to be troubled by dyspnoea.

April 25th. Was again aspirated, and sixty-three ounces of pus taken out; the patient standing the operation very well.

May 1st. Has been steadily gaining in strength, but begins to be troubled by the fluid.

May 6th. Drew off fifty-eight ounces of pus by aspiration. The operation was well borne.

May 7th. Is beginning to sit up, appetite good, and sleeps well; brandy stopped altogether.

May 15th. Patient sits up all day, and feels very well; only tonics continued.

June 8th. Aspirated, and twelve ounces of pus taken out.

June 20th. He is feeling so well, that he wishes to go home.

Examination shows, posteriorly, over the left lung flatness over the lower fifth; above slightly tympanitic. Absence of percussion note, and absence of respiratory sound below the level of the fluid. On the right side, the percussion note was hyperresonant, and there was exaggerated breathing. In front on the left side, percus-

sion sound slightly dull as far as the third rib, where the dulness begins to be well marked. At the apex of the right lung slight dulness and broncho-vascular respiration; below the breathing is exaggerated. Sucktion very feeble.

June 21st. Refuses to remain any longer, and so was discharged. Feels quite strong, appetite good, and sleeps well; very little cough.

The patient came to see me on July 12th, and there had been a great improvement since he left the hospital; he had gained in flesh, and was feeling quite well.

Examination showed about the same condition as when he was discharged; there did not seem to be any increase in the amount of fluid. He was readmitted to the hospital October 21st. He said that he had been doing nicely until the first of September, when he began to be troubled by dyspnoea and cough. His appetite failed, and he could not sleep. These symptoms gradually grew worse until his admission; when he was found suffering from intense dyspnoea, and could only lie on his left side. The left side of his neck and face was markedly cyanotic and oedematous. There was considerable bulging of the left side of the chest, with distinct pulsation. The minute line was over the whole lung, extending about two inches below the twelfth rib, in the axillary line. When the hand was applied to the surface, a marked heaving impulse was transmitted to it. Auscultation over the tumor gave negative results. Of course aneurism was considered, but its existence was considered very improbable.

The right lung was emphysematous. Apex-beat beyond the right nipple. Dr. dressing was called for, after drawing off a syringeful of pus by the hypodermic needle, decided to operate at once by free incision (October 21st, 5:30 P.M.). The patient being so weak no anaesthetic was used.

In view of the extraordinary symptoms attached to the case, it was decided to make a small opening with a scalpel, and then to probe it. The cavity was opened, and a large quantity of pus was withdrawn. The cavity was washed out with water the temperature of the body and a drainage-tube inserted. After this he felt very comfortable.

October 23rd. Patient has slept about six hours during the night. The dressings being removed, about twenty-five ounces of pus were discharged. The cavity was washed out with water the temperature of the body and a drainage-tube inserted. After this he felt very comfortable.

October 24th. Wound dressed twice a day, still considerable discharge. Patient feels a little better, but his appetite is poor and stomach very irritable. Temperature normal. Pulse rapid and weak.

October 27th. Has improved very slowly, but sleeps well. Cavity only washed out once a day, discharge diminishing.

November 2d. Discharge less, but he has no appetite, has colliquative diarrhoea.

From this time his diarrhoea persisted, despite remedial measures, and he remained weak. He gradually became weaker until November 16, 1881, when he died from exhaustion at 11:20 P.M.

At the autopsy, twelve hours after death, the body was
very much emaciated. The diaphragm extended to the sixth rib on the left side, and the fifth on the right. The incision was just below the twelfth rib, two and a half inches from the spine, and in the most dependent portion of the cavity. The left pleural cavity contained several large clots of blood, but no pus; and was covered with an old, thick, purulent exudate. Careful investigation failed to show the source of the hemorrhage. The lung was in a complete state of atelec-
tasis, consisting only of a mass of slate-colored indurated tissue, about the size of a hand, having a few small cavities in the apex. The right lung was emphysematous and partly collapsed. The heart was pale and flabby, and firmly united to the pericardium by adhesions. The valves were normal, but there was commencing atheroma in the aorta. Liver fatty-and slightly enlarged. Spleen and kidneys pale, otherwise normal.

Progress of Medical Science.

VACCINATION AND VARIOLE.—In a recently published report, Dr. Voigt, the Superintendent of the Vaccine Institute at Hamburg, sums up the results of his observations under nine heads, which may be looked upon as an epitome of the whole question (British Medical Journal, December 22, 1883). 1. It is possible to create vaccine by the inoculation of the calf with lymph from the pus-
tules of human beings the subjects of small-pox, but suc-
cess from last winter and expected in every case. 2. The energy of variola-vaccine obtained in this way is such that it is not fit for the purpose of vaccinating human beings un-
til it has been several times transmitted from calf to calf, or from ox to ox, and its intensity has been thus dimin-
ished. 3. In the first year this new lymph has a greater protective power than animal lymph of older stocks. 4. Vaccination is derived entirely from the same contagium, and give to those affected by them an in-
immunity one against the other. 5. The duration of this immunity depends on the intensity of the pathological process. 6. After the lapse of twelve years, persons who have been attacked with small-pox show the same sus-
cceptibility to vaccination as those who have been vac-
cinated at an early age. 7. Consequently children of twelve years of age, vaccinated in infancy, present a moderately favorable soil for the poison of small-pox. 7. Therefore, revaccination of all children at or even after the age of twelve is highly to be recom-
manded. 8. Animal lymph, originally very active, di-
mits sooner in efficacy when transmitted from calf to calf sooner than lymph derived from the arm to arm. On the whole, i.e., after a long time, human lymph gives better results both in man and beast; whence it follows that animal lymph from old stocks gives less success than revaccination of the first generation. 9. Carefully generated, and in well-ventilated and regulated stalls, variola-vaccine is the most energetic of all, not only when taken directly from the calf, but especially in its humanized form. Consequently if we would obtain the most powerfully protective lymph we should, when occasion offers, from time to time, reproduce a stock of variola-vaccine.

CHARCOT'S JOINT DISEASE.—At a recent meeting of the Pathological Society (London Lancet, November 24, 1883), Dr. Hale White showed a pelvis taken from a subject which was brought into the Guy's dissecting-
room last week, and which he thought was an example of Charcot's disease. The bones were extremely thin and light, the spaces in the cancellous tissue being un-
usually large. This change made the bones so light that the whole pelvis weighed only seven ounces. The acetabula were much altered, the walls being as thin as paper in many parts. Owing to this tenacity of the bone, the heads of the femur had pressed the bottom of the acetabula into the pelvis, thus forming two very promi-
nent bones in its interior, and making the transverse diameter of the brim three inches and a quarter. All articular cartilage had disappeared. This deepening of the cavity made its margins very prominent, so that the anterior superior spine quite overhung the acetabulum on the right side; at the back part the deepening was so extreme that the thick portion of the bone between the acetabula and posterior surface of the ischium was almost worn through. On both sides, especially the right, it was seen that the deepened cavity was divided into two parts by a vertical ridge placed opposite the most superior part of the ischial tuberosity; the anterior of these two parts was the lesser trochanter to play in the absorption of the neck of the femur was so great that the lesser trochanter was brought up to the margin of the obturator foramen. The chief points about the specimen were the great atrophy of bone without the formation of any new bone, thus corresponding exactly to Professor Charcot's description of "considerable atrophy without the production of 'stalactites.'"

ELEPHANTIASIS ARABUM CURED BY LIGATION OF THE MAJOR ARTERY.—In view of the fact that the successful operation has been performed in this country and in Europe, for the cure of this most obstinate disease of the lower ex-
tremity, by ligation of the femoral artery, are quite few, and because of the apparent propriety of resorting to this last method before amputation becomes an impious necessity to save the life of the patient, the successful case operated upon by Dr. C. E. Weber, reported in the number of The American Journal of the Medical Sciences, has considerable interest. Thirty days after the operation the limb had diminished in circumference nearly one-half, and at the end of six months the patient reported that he suffered no inconvenience whatever from his limb, save that upon unusual exertion a slight edematous swelling would supervene.

INFECTIONS AND EMBOLISM OF VARIOUS ORGANS.—Professor D. J. Hamilton concludes from a paper on the above subject: 1. That infarctions of the spleen and kidneys are due to the blood-supply being cut off from the part, and the most common source of this is embolic plugging of the respective arteries. 2. They are not usually accompanied by hemorrhage, unless in the zone of inflammation which surrounds them, although congestion and punctiform extravasation are possibilities in the early stages. 3. They are caused by changes within them resembling those which follow the total abstraction of the blood-supply in other parts of the body. 4. They are in course of time absorbed and the formation of a depressed cicatrix follows. 5. Em-
bolism of the arteries of the brain is accompanied by a similar necrosis, but, as the arteries of the encephalon are terminal only in certain regions, the necrosis of the part supplied by an occluded artery is never so wide-
spread as in the case of the spleen and kidney. Hem-
orrhages may occur here owing to the attempt to nourish the part by collateral channels. 6. The hemor-
rhagic infarction of the lung is simply an apoplexy due to its causes, but by far the more common is rupture of collateral vessels unduly distended by regurgitant pres-
sure from valvular disease of the heart. Its wedge shape is caused by the shape of the bronchus and air-vesicles in which the effused blood is contained, and not by the distribution of a terminal branch of the pulmonary artery. The lesion usually has nothing to do with pulmonary artery embolism, but a venous, rather than a capillary, course. If there is a perilung block the usual character of a hemorrhagic infarction. 7. The blood in these pulmonary infarctions is usually absorbed, and no trace of their former existence remains.—Liverpool Medical-Chirurgical Journal, July, 1883.

PHYSIOLOGY AT OXFORD.—A decree has been passed, appropriating $50,000 to establish a physiological labora-
tory at Oxford. Dr. Burdon-Sanderson is Professor.
THE THERAPEUTIC VALUE OF HYPNOTISM.

It is related of the late Dr. Beard that some one going into his clinic room at the Demit Dispensary found him making extraordinary motions and gesticulations and using such incoherent language that for a moment it was thought he was insane. It was explained, however, that he was only giving what the patient thought was electricity, and the hypometabolic fluid was acting remarkably well. For some time Dr. Beard treated numerous cases of paralysis, rheumatic, neuralgic, and hysterical troubles by these expectant and hypnotic methods. It was a kind of scientific faith-cure.

When mesmerism, having been introduced into England, was scientifically studied by Braid, that observer claimed for it wonderful therapeutic effects. Many of his cases, however, were reported in an uncritical manner, and the claims which he advanced were altogether too large. We believe that even before this time attempts were made to treat all kinds of diseases with "mesmerism" or "Braidism," and separate wards in hospitals were even assigned for this specific purpose. It had a therapeutic run very much like that of the Perkin's tractors years before.

Since the Germans took up the subject of hypnotism, four years ago, a few careful experiments have been made to test its therapeutic efficiency. Berger, in 1888, reported some cases of hysterical contracture, of hystero-epilepsy, and of hysterical mania, relieved by putting the patients into hypnotic sleep.

Dr. Creutzfeldt, assistant to Professor Preyer, reports some cases (Preyer, "Der Hypnotism," Berlin, 1882) of neuralgia relieved by hypnosis. Dr. L. E. Fischer reported similar cases in 1883, and Rieger, of Jena, very recently reports cases of spasmodic troubles and of hysterical mania relieved by the same process.

In the Berliner Klinischer Wochenschrift for January 21st, Dr. A. Wiebe, of Freiburg, reports four cases in the clinic of Professor Balümer, where he had applied mesmeric passes for the relief of various troubles. Two of the cases were hysterical patients suffering from clonic spasms of a violent and persistent character. The first was cured, the second relieved. The third was a case of functional hemianalgesia and hemianesthesia, occurring in an apparently healthy girl. This case was also cured. The fourth case was one of trigeminal and brachial neuralgia, which had been first treated with counter-irritants, electricity, and various internal reme-
tic of any chemical principle with which we are acquainted. Another error into which physiological chemists have fallen is that of calling the so-called amyloid matter an “albuminous” matter, an error dating from the results of Prof. Kekulé’s analysis of an amyloid liver treated by extraction with caustic alkali and subsequent precipitation by an acid. Naturally and necessarily, continues Thudichum, the precipitate had the composition of albuminous matter. True amyloid matter, however, is not precipitated by caustic alkali, nor does it contain nitrogen, and it is very probable that it is nearly related to, if not identical with cellulose. Certainly no similarity exists between it and the product of parenchymatous changes of the various organs which have been called amyloid matter.

It would be interesting to notice Dr. Thudichum’s remarks concerning the cerebroside or cerebral amylosides in their relation to cerebrocerebro diabetes, a kind of acute glycosuria, but space does not permit. We pass, therefore, to a consideration of the phosphorized and nitrogenized principles of the brain. These principles, by their faculty of assuming and maintaining the colloidal state, may be said to build up the nerve-fibres and the accumulation of nerve-fibres known as nerve-centres, which enable the brain to maintain its accurate distribution in the cranial cavity. Not only is Thudichum willing to admit the truth of Moleschott’s aphorism, “no thought without phosphorus,” but he thinks it highly probable that phosphorus, the ingredient of the brain present in smallest quantity, may be the most indispensable. The phosphorized substances are present in all nerve-matter, particularly in the gray substance; and are found in every centre of life-action. Bearing this in mind, and considering that, in the water-swelled colloidal state, these substances combine with almost all chemical reagents with which they come in contact, provided these reagents are in relative excess, and that the combinations are broken up by a simple process of dialysis, we have a key to the raison d’être of a great deal of brain disease—probably also to diseases not referred to the brain.

For the present purposes, says Thudichum, we may lay aside our knowledge of the anatomy of the brain, and consider it a mere lump of matter, endowed with chemical properties maintained by its own life—or as a colloidal septum with arterial blood on one side and venous blood and cerebro-spinal fluid on the other. If now, the blood carries a lead-salt to the brain or nerve, a combination is immediately formed between it and the cephalin or myelin; the combination with myelin being very stable, that with cephalin quite unstable. Other proximate principles, such as lecithin, apomyelin, and anilin do not combine with the lead-salts. The reason is apparent. Cephalin and myelin have acid characteristics; myelin, indeed, behaves as a dibasic acid, while in lecithin, apomyelin, and anilin the alkaloidal character prevails, and these bodies combine more readily with alkaloidal reagents, as cadmium chloride, platinum chloride, etc. Recognizing lead-poisoning, therefore, as nerve-poisoning (from the formation of lead salts with cephalin and myelin), our therapeutics must be directed toward breaking up these combinations by the administration of an agent which will itself be broken up by contact with the lead and form another lead-salt. In seeking for this agent we find that we have been anticipated. Iodide of potassium has long been recognized as an efficient agent in chronic lead-poisoning. It is known, too, that it will act more readily when large quantities of water are administered with it. From a chemical point of view it will be seen that a better antidote to lead-poisoning could scarcely be given than iodide of potassium and large quantities of water; for iodide of potassium being comparatively unstable, the contact of a solution of it with a solution of a lead-salt, immediately causes the formation of iodide of lead, thus setting free the potassium. The water administered now comes in for its share of the work. The vessels are deluged with a solution of potash, a highly diffusible liquid, and a stimulant of liquid secretion. The iodide of lead is soluble in the potash solution, and fresh quantities of potassium iodide being constantly added to break up the new combinations between the lead solution and the cephalin and myelin, the system is gradually rid of the offending substance. We have thus a rational basis for the administration of potassium iodide in lead-poisoning.

A very remarkable combining power exists between almost all the specific nerve-principles and alcohol. We find such a state of combination of alcohol and the phosphorized principles and cerebroside in chronic alcoholism. It was shown by Percy, in 1839, that in alcoholic poisoning a large quantity of alcohol is found in the brain-substance, and more recently that nerve-substance absorbs it more readily and to a greater extent than does any other tissue of the body. The alcohol in the tissues being removable by dissociation or washing out by means of large quantities of water introduced into the blood, we need go no further for a chemical agent to effect this. But water will not cure such pathological changes as are cirrhotic, and we know that alcohol tends especially to cause cirrhotic conditions. Nor do we know of any agent which will cure them. It is seldom that the victims of chronic alcoholic poisoning can take large quantities of water. Their digestive organs have to be toned up to it by beef-tea, coffee, and easily digested and stimulating food. In acute alcoholic poisoning it is suggested that we abstract blood from a vein, and inject saline solutions containing some form of ammonia. For all therapeutic means which we have yet administered to combat the effects of a “drunk,” the ammonia compounds, especially the aromatic spirit, stand first in point of value.

MEDICAL EDUCATION IN CANADA.

The medical schools in the Dominion of Canada compare favorably with those in other countries. The cities are smaller, and in this respect may not afford as good a field for practical teaching as is to be found in the larger centres; yet their material, as far as it goes, is very thoroughly used. It does not follow that because a city is large the advantages in practical work must be greater than in a smaller one.

There is now, and for some time past, a distinct tendency toward the practical in medical teaching. While didactic lectures are still given, and perhaps with greater care and zeal than ever, there is added that other great factor in medical education—observation. The various schools vie with each other in the efficiency of the prac-
tical department of the work. The anatomy is being taught very much by constant demonstrations, the microscope is placed in the hands of every student, and the test-tube is as familiar as the scalpel. This change has been brought about mainly by the changes in the course of study and the mode of examinations. The qualifying bodies now require that a fair percentage of the lectures must be practical. Whenever the dissected subject was used to examine candidates upon in the various years, students found it to their best interest to spend much of their time in the dissecting-room; and, instead of avoiding this part of the work, there was a run for material and practical teaching.

When the bedside test of the student was inserted as part of the examination, clinics became a great necessity; and so more of the school men began giving this department a larger share of their time and attention. No matter how anxious the teachers may be to impart instruction, or students to acquire it, the plan of Canadian hospitals can hardly be regarded as ideal in respect. The advances which have been made in medical education necessitate better and more efficiently equipped schools; but there is not so much hope for larger and better arranged hospitals. These latter are intended for the sick, and so long as they meet public wants in this respect, no great change need be looked for. The material at the command of nearly all the medical schools is quite up to their requirements, and is very thoroughly used, notwithstanding many obstacles.

The entrance examination, fixed by the different licensing, or degree-granting bodies, is fairly high. It compares well with that found in Great Britain. This part of the course is very compulsory; for none can enter upon their studies and obtain a qualification in medicine without it. This preliminary examination being over, the course consists in four winter sessions. The examinations differ in different universities and licensing bodies. In some the work is divided into a primary and final group of studies, while in others there is an annual examination at the close of each session.

From a somewhat extended acquaintance with the state of medical education in the United States (and in Great Britain, we cannot but think that Canada compares very favorably with both. It must be admitted that such old and large centres as Edinburgh, London, New York, and Philadelphia would have advantages peculiarly their own. Yet when we look at the advantages and disadvantages to medical education in Canada, at the careful manner in which both theoretical and practical teaching is given, at the high standard fixed by the different curricula, it must be admitted that these schools are turning out a very efficient class of practitioners.

If there be any serious error in the Canadian system of medical education, it is rather one of excess than one of defect. Several of the branches of study might, perhaps, be dropped out of the course altogether; or at least less attention paid to them. Such subjects as botany, zoology, and chemistry cannot be regarded of such prime importance as physiology and anatomy, and yet at present they receive a very great deal of attention. Pathology lately has been assuming its true position by receiving something like the attention it deserves.

THE PREACHER AND THE QUACK.

The watchman cries, "What of the night?" in one column, and proclaims a cure for gonorrhoea in another. When the "morning comes," the reading of "Paradise Lost" is next in order. The "Evangelist" descends to earth to cure cancer, and the "Christian Intelligencer," the avowed advocate of the pure and the good, stands upon the ramparts of Christendom holding the Bible in one hand, a kidney cure in the other, and warning all to flee from the wrath to come. In a recent issue of this model Christian intelligence disseminator, and spliced between columns advertising Paul's departure from Corinth, lessons for to-day, and the influence of Christian wives, on the one hand; and pile cures, consumption arresters, and blood-purifiers on the other, is an account of a prophecy which, in substance, declares that when Mars, Neptune, Jupiter, and Saturn dance around the sun, that the moon will eventually fulfill its ultimate destiny, and a terrible atmospheric upset will eventuate. As a consequence, much sickness will prevail, and death and desolation will culminate in a grand Black Friday for the unfittest. "But," soberly says the "Intelligencer," "we are told for our comfort that the strong and pure-blooded need have little to fear in these calamities," and that it is only necessary to keep the liver and kidney in good condition by a sure-cure kidney-remedy. We do not mean to say that this is not paid for, so much per line; but the good editor has not spent long enough to appear at his ease when at supper. Under the lessons of the day we learn, that "those who have heard the gospel have themselves to blame if they are not saved," and in the next column the devil mounts the pulpit and tells the congregation how it is done. Again, the lesson in the previous column significantly says: "Laborers for Christ need our hearty sympathy," and we presume, therefore, that they get it. And "the greatest of these is charity," in helping along the benefactor of his kind. It is sweet also to learn, in glancing from the purusal of the moon dance and the medicine bottle, that "friendships founded on common love for Christ are strong and tender." Therefore we do not think it likely that the man with the bottle and the man with the Bible are likely to fall out.

MEDICAL TEACHERS IN FRANCE AND GERMANY.—

There are 154 professors, while in France there are only 134 for all the schools of medicine. Germany spends over $3,000,000 annually on its professors, while France spends one million less.
THE MEDICAL RECORD.

THE POSSIBILITY OF PULMONARY COLLAPSE AFTER AN INFANT HAS BREATHE.

It is quite commonly supposed that a new-born child has not breathed if the lungs, when placed in water, will sink. Yet it may happen that the lungs of a child which has not only breathed, but cried, may after the death of the infant be found collapsed and so empty of air as to sink under water. This fact was noticed as much as two centuries ago by Zeller, and since his time numerous confirmatory observations have been recorded. But though the fact is undoubted, the explanation of the manner in which the secondary collapse occurs is not easy. Maschka is of the opinion that cries and other sounds can be produced by a small quantity of air in the trachea and larger bronchi, without any actual entrance of air into the lungs. Another view is that of Thomas, who has suggested that the inspiratory efforts in a weakly child may become so feeble after a while that more air is expelled than is inhaled with each respiratory act, and soon the elasticity of the lungs drives out the residual air, whereupon the lungs return to their pre-natal condition. Maschka denies the possibility of such an occurrence, since no amount of pressure can squeeze the air from the lungs when it has once entered. Schroeder, however, agrees with Thomas, and answers Maschka’s objection by the supposition that, in the case of pressure upon the lungs, the bronchi are compressed and the air prevented from escaping.

The latest contribution to this somewhat puzzling subject is that of Dr. Ungar, of Bonn (Centralblatt für Gynäkologie, December 8, 1883). He seeks for an explanation of the airless condition of the lungs in children who have once breathed in a study of pathological atelectasis. The theory of Bartels, that in this disease the air of the compressed portion of lung is absorbed from the alveoli by the blood of the capillaries, has been confirmed experimentally by Litcher. But in the case of acquired atelectasis it is only a portion of the lung that is collapsed and not the whole of both lungs, and it might be questioned how far this process could go before it would be terminated by resistance of the thoracic walls or by an arrest of the blood circulation. These objections were, however, anticipated by Ungar. He found, by actual experiment on new-born animals, that the chest walls readily followed the collapsing lungs, being forced to do so by atmospheric pressure. Regarding the second point, he instances the power of resistance to asphyxiating influences possessed by the new-born child, and relates a number of cases in which the heart continued to beat for a considerable time, even several hours, after the cessation of respiration. The process of the return of the lungs to the fetal state is a very gradual one. As the respiratory movements little by little lose intensity and force, more and more of the pulmonary lobules become deprived of air, until, at the time when respiration has entirely ceased, but a very small portion of expanded lung remains. The blood circulation continues, however, for some time, and the air still remaining in the lungs is absorbed. The author succeeded in obtaining nearly complete atelectasis in young oxygen-breathing animals by causing a cessation of respiration by curare. When the conditions of absorption were less favorable, as in animals breathing ordinary atmospheric air, the collapse of the lungs was less marked. When the curare poisoning was combined with pressure upon the chest and abdomen, so applied as to aid in the expulsion of air and to restrain the inspiratory movements, the most complete atelectasis was produced.

Ungar’s theory of the production of this condition is plausible and seems reasonable enough. But the important fact to be remembered is that this return of the lungs to the fetal state may occur. Hence it cannot be said with certainty, when the lungs of a new-born infant are found void of air, that the child has never breathed. At most it can be claimed that there is no evidence of its having breathed. Cases have arisen, where it has been of the greatest importance to determine this very point, and if it should be decided in the negative upon the evidence of the collapsed lungs, injustice might readily be done. Another practical point to be remembered is that the presence of but little air in the pulmonary vesicles is of itself no positive proof that the respiratory efforts were weak or of very short duration.

THE DRUGGISTS’ PROTECTIVE UNION.

The druggists of this city and vicinity have united to form a protective union. The object of this is to keep up the prices, certain adventurous parties having ventured to sell drugs at a less profit than one hundred and fifty per cent. Druggists claim that their individual receipts are small, therefore they must make a large profit. It is only fair, also, to allow a large part of the so-called profit to represent the skilled labor employed.

Notwithstanding all this, the druggists’ charges in this city are beyond reason, and the “protective union” is simply a sign that the public is beginning to appreciate the fact. The drug trade is overcrowded, and the excessive competition must lead to cutting. It is impossible for any “unions” to avoid this. The organization of druggists, therefore, in order to keep up the prices need not be particularly condemned, as it will surely prove futile.

ATTENUATING VIRUS BY DILUTION.

Pasteur attenuates virus by exposure to the influence of oxygen. Toussaint and Chauveau attenuate anthrax virus by subjecting it for a few minutes to a temperature just below what is necessary to destroy it. Thus, in order to get a weak virus they heat it to 50° C. for fifteen minutes.

Both the above methods, however, require a great deal of skill, and in each case the virus may lose its activity very soon. Dr. D. E. Salmon has developed what he states is a new method of attenuation, and one which has been very successful with chicken cholera. “It consists essentially in inoculating with diluted virus; but, of course, to produce a definite result, the virus to be diluted must be of a standard strength. When sufficiently diluted, the general disease is not produced, but simply a slight local irritation characterized by distention of the blood-vessels and a scarcely visible swelling. This remains for about three weeks, without affecting the general health in the least, and, when it disappears, the bird may be inoculated with the strongest virus and resist it in the most perfect manner.”
This method of attenuating virus can, however, hardly be considered original.

In the Archivés Générales de Médecine, a year ago, Dr. Leblanc gave an account of the experiments of Professor Peuch, of Toulouse, with the virus of ovine variola (La Clavelée). This he inoculated in various dilutions. The protective influence, however, was not found to be great, and we very much doubt whether by a simple process of dilution a trustworthy protective virus can be obtained.

**News of the Week.**

**Medical Paris.—** At the meeting of the Académie de Médecine, February 12th, M. Constantine Paul exhibited a new form of surface thermometer. The bulb of the thermometer is placed at the bottom of a hollow soft-rubber cone, which is connected by a tube to a rubber exhaust-bag. The cone is applied to the skin and the air exhausted on the principle of a dry cup. The instrument can be applied to any of the soft parts except where there is hair. M. Fétrol related the history of a patient who had suffered from pulsatile empyema, and who had been cured by Estlander's operation. M. Bouchard gave an account of an experimental study of the effect of the hypodermic injection of chloroform and chloroform albuminura. The Society then discussed the subject of the law regulating the committement of the insane.

**Dr. Mendez Alvaro, of Madrid, Spain, died on December 19, 1883.** He was founder of the Spanish Society of Hygiene, President of the Royal Academy of Medicine, and director of the journal El Siglo Medico. He was a prolific writer and translator, and was author of a manual of auscultation.

**Medicine in Fiction.—** M. Emil Zola in order to enlarge the sphere of his lascivious realism has introduced medical pictures into his later novels. He leads off with a description of an epileptic fit and delirium tremens. In his "Pot-Bouille," he gives a description of an accouchement, in which a poor girl delivers herself of an infant without medical assistance. In "La Joie de Vivre," he goes further and describes a lying-in scene where there is a cross-birth and a shoulder presentation. The medical attendant has never seen such a case before, and is much disturbed. He, however, performs version and safely delivers the child.

**Medical Vienna.—** At the meeting of the Society of Physicians of Vienna, February 1st, Professor Kundrat exhibited post-mortem specimens showing a rupture of the left auricle. The patient, a powerful man, was shot in the left side, the bullet lodging in the sixth rib. Death ensued in a few days. A rupture was found in the left auricle, due to the violent concussion and shock of the bullet. Kundrat also showed the specimens in the case of a man, aged twenty-eight, who had suffered from right-sided pleurisy, for which he had twice been tapped and three or four pints of sero-sanguineous fluid removed. Upon his death, five and one-half weeks later, the right pleural cavity was found filled with a lympho-sarcoma-tous growth. Dr. Zillner showed several preparations illustrating heart injuries. Dr. Engiisch read a paper upon "Albuminuria in Incarcerated Hernia." He had found that in cases of incarcerated hernia albumen was found in the urine, and that the amount increased with the duration of the incarceration. The age of the patient and of the hernia, as well as its contents, made no difference in the amount of urine. Professor Nothnagel thought that the albuminuria was due to the diminution in arterial pressure—not to any change in anatomical relations.

**The Sims Memorial Fund.—** The Kings County (N. Y.) Medical Society adopted a resolution at its February meeting, appointing a committee consisting of Drs. Alex. J. C. Skene, Samuel G. Armor, and Paul H. Kretzschmar, to collect from members for the Sims Memorial Fund. The circular contains the original appeal of the General Committee, and encloses a suitable blank for the name of the subscriber. This is an excellent idea, and other county societies would do well to imitate this laudable example. There is no doubt that the Kings County Society will show a proper record.

**The Albany Medical College held its commencement exercises at Music Hall, on Wednesday evening, March 5th.**

**Dr. Edward S. Peck, of this city, has just given a course of lectures on the anatomical and clinical relations of the eye and ear to the teeth, at the New York College of Dentistry, Second Avenue and Twenty-third Street.** The present class numbers about one hundred and twenty-five students, of whom nearly sixty will present themselves for graduation at the coming commencement.

**Medical Bills in Congress.—** The following medical bills have been recently introduced in Congress:

House Resolution 71. That it shall be a misdemeanor, punishable by a fine of $500 and dismissal from office, for any Government, civil, or military officer to make discrimination in favor or against any school of medical practice, or its diplomas or graduated members, in the examination and appointment of candidates to medical service in any of the departments of the Government. That all such examinations shall be open, and detailed records of said examinations shall be placed on file in the Congressional Library, subject to inspection and use of members of Congress.

H. R. 1,807. To prevent the use of U. S. mails to advertise noxious and dangerous medicines, foods, and compounds. It provides that after six months from approval of the Act no advertisement of any kind or nature, or advertising device of any medical preparation, compound, or prescription, or any punch, bitters, cordial, or similar compound or preparation, to be used as medicine, or mixed with food, liquor, wine, or other substance, shall be placed in or carried by the mails, until exact formula with sample be placed in the Patent Office, and a certificate is issued by said Patent Office, that the same is not noxious or dangerous to health. A fee of $20 is charged for the certificate, and a penalty of from $100 to $1,000, or the penitentiary for six to twelve months, for violation of the law is imposed. Experts are to be employed by the Patent Office to make the proper examination.

S. 1,044. To establish a university of medicine at the
Capital, for the advancement of science and the discovery of improved methods of treatment and cure of disease. It appropriates $1,000,000 as a perpetual endowment, and $100,000 for the erection of buildings and purchase of grounds. The professors' chairs shall be open to all schools of medicine, and all methods of treatment and cure of disease.

S. 1,223. That all appointments to medical service under the Government shall be made from graduates of legally chartered medical institutions, without discrimination for or against any school or theory of medical practice.

H. R. 1,791 forfeits the corporate powers of any association in the District of Columbia which shall withhold any privileges of membership from any person on account of such person being in the service of the United States. The object of this bill is directed against one of the rules of the Medical Association of the District of Columbia which prevents those members from voting who are in Government employ.

A resolution has been referred to the Committee on Agriculture with power to send for persons and papers, instructing said committee to inquire into and investigate the question of the adulteration of dairy products with oleomargarine, butterine, suine, etc. The resolution was placed on the calendar and ordered printed.

A SUBSTITUTE FOR THE NATIONAL BOARD OF HEALTH'S BILL now before Congress, "for the prevention of the introduction and spread of contagious infectious diseases," was handed to the Committee of Public Health at its last meeting. This substitute contemplates the forming of a United States Board of Health; gives the quarantine work to the Treasury Department and the investigation into sanitary matters to the Navy Department; the Board to consist of the Surgeons-General of the Army, Navy, and Marine Hospital Service.

THE Third International Otolological Congress will be held at Basle, Switzerland, September 1 to 4, 1884. Gentlemen wishing to read papers at the meeting are requested to communicate the subjects which they intend to treat by May 15, 1884. Besides papers and discussions it is proposed to exhibit instruments and preparations both macroscopic and microscopic. All communications concerning the Congress should be addressed to Monsieur le Docteur Burckhardt-Mérian, Bâle (Suisse).

THE College of Midwifery of New York still continues to send its advertising pamphlets to the profession, including an offer of "confidential" percentages to medical men. Accompanying these is the professional card of a gentleman who resigned some time since from the institution. And thus the so-called "woman's work" goes on.

It has been heard from in several parts of the country late. Dr. Sarah E. Post, of this city, writes that her name as a member of this faculty is published without authority, she never having accepted such an honor. Are there any more to be heard from? No institution started with better promises than did the College of Midwifery, and none has more utterly failed in its so-called ultimate aims. The profession looks upon it as utterly dead, and thinks that it is about time, with its originators, it should be buried. We are surprised to learn that a new bill to incorporate this institution is before the State legislature. The incorporators are all laymen, with one exception. It appears to be the intention of the bill to give this college extraordinary powers for licensing midwives, without allowing the medical profession to have any voice in the matter. The bill should not be allowed to pass under any consideration.

THE New York Skin and Cancer Hospital.—The position made vacant by the resignation of Dr. Hunter has been filled by the appointment of Dr. J. E. Janvrin, with Dr. J. R. Goffe as his assistant.

The Sixth Annual Meeting of the Sanitary Council of the Mississippi Valley will be held in the city of Memphis, Tenn., on Wednesday, March 19, 1884.

Rise in the Price of Quinine.—It is reported that owing to the fire which destroyed the establishment of Powers & Weightman, together with large quantities of Peruvian bark, there will be a rise in the price of quinine amounting to about fifty cents.

Syphilis from Cigar Stumps.—The following letter appeared in a recent issue of the Times: "A prominent physician told me lately that, from the practice of cigar-makers wetting the wrapper with their saliva and biting the end of the cigar into shape, a spread of syphilitic disease was taking place; that he knew of several cases. Somewhat alarmed, I managed to visit a number of factories. Two-thirds of the cigar-makers, I found, daub the whole end of the cigar with their saliva. Thinking that Cuban workmen might not do it, I visited places where they were employed, and found that not only did they use their saliva to make the wrapper stick, but that most of them before wrapping bit the end of the cigar into shape with their teeth. As the physician informs me that many of the cigar-makers have sore mouths from disease, it is a dangerous as well as a beastly habit." We should like to hear from the prominent physician who knows of several cases. We believe that all medical literature furnishes only "several cases."

The Philadelphia Clinical Society has been organized in order to give women physicians an opportunity to become members of an active organization.

News from the German Cholera Commission.—Incomplete reports are telegraphed to the effect that Dr. Koch and his co-workers, in India, have found a germ which they believe to be that of cholera. It is found only in cholera cases. It has been cultivated but not yet successfully inoculated in the lower animals.

Oleomargarine and Butterine.—The Senate Committee on Public Health have been investigating the subject of adulterations in butter with interesting results. About a million and a half pounds of imitation butter is sent into New York annually, a large part of it coming from the West. Two-thirds of the ordinary butter of the grocer's is imitation. Butterine is made from lard and butter, colored with annatto, and subjected to certain processes of melting and cooling by which the ingredients are amalgamated. Oleomargarine, which is more notorious in the market than any other form of imitation butter, is made from beef-fat by various processes, the secret of each being carefully guarded as a trade receipt, although the general features of the rendering are well
known. These imitations, when carefully made, are
harmless, but they ought to be made under official inspec-
tion.

THE TRANSMISSION BY MAN OF PHYSICAL INJURIES.
—Doubtless many have wondered why, since in lower
animals physical injuries are transmitted, it happens that
the Jews continue to be born with fore-skins. Instances
of inheritance of physical injuries are occasionally re-
ported. Mr. Irving P. Bishop relates a case of this kind
(Science, February 8th). A gentleman acquired a pro-
nounced deformity of the foot by wearing a tight boot
when seven years old. He has seven children, of whom
two inherited the crooked toe.

THE BACILLUS OF RINDERFEST.—Dr. Metzendorf, of
Breslau, has discovered and cultivated the bacillus of
rinderpest.

A STUDIOS PROFESSION.—Over eight hundred doctors
in this city are studying German.

MEDICINE IN PATERN, N. J.—A correspondent of the
Philadelphia Medical Times writes rather gloomily
concerning the literary and medical status of Patern,
N. J. "Perhaps no city of its size in the United States is
so destitute of literature and reading as this one. There
is no public library of any description worthy the name.
The only attempt in that direction is a motley collection
of old books—perhaps one hundred in all—open once a
week in the evening, in the basement of one of the
churches. The opportunities for mutual or individual
improvement to physicians are most meagre. The
County Medical Society, while having upon its rolls up-
ward of forty names, cannot usually muster over half
a dozen members at a regular monthly meeting; and the
details are uniformly uninteresting and unprofitable, con-
sisting chiefly of routine business. All the sociability to
speak of in the profession finds expression in an annual
dinner at the leading hotel. The prevailing idea in the
minds of most of the members appears to be business.
This dominates all else. The facilities for the succor of
the homeless sick and mained consist of two general
hospitals and one infirmary for diseases of the eye and
ear. The former two have been in existence about ten
years, the last about one year. The city has a very good
Board of Health."

SHOCK AS A THERAPEUTIC AGENT.—The history of
the chronic insane patient who was cured by a blow on
his head is a familiar one. Traumatism certainly has
relieved cerebral troubles in a few cases; it has produced
opposite results in many others. In fact, injury of the
head is a recognized cause of insanity, inebrity, and all
the grave neuroses. Recently we have had illustrations
of the effect of blows upon the head in relieving distur-
bances of the special senses. A man who had been quite
deaf stumbled while entering a door and fell, striking his
head upon the door sill. He received a bad bruise, but
he was relieved of his deafness. A more notable case is
that of Mr. Maybee, of Long Island, an old gentleman
who had for several years suffered from spinal disease,
and who had been blind for a year. He was beaten
about the head by tramps, who killed his wife and daugh-
ter. He lost some blood and had a considerable scalp-
ound. A few days later he began to recover his eye-
sight, and his vision improved until he could see tolerably
well. The explanations offered have been that he had an
optic neuritis, and the shock stimulated the atro-
phied nerve or modified its conductivity; or that he had
a cataract, which was dislocated by the blows and vio-
ence that he received.

CONSERVATISM.—The following notice appears upon
the bulletin board of one of the leading city medical
colleges:

"Attention is called to the rule of this college which
forbids the attendance of women at either didactic or
clinical lectures in this institution."

GLANDERS has appeared among the horses of Chicago.

PERSONS MURDERED FOR DISSECTING PURPOSES.—It
is claimed that two colored persons were murdered and
their bodies sold to a medical college in Cincinnati.
The parties are under arrest.

DECISION UPON AN ANATOMY ACT.—The law of Mary-
land makes it a criminal offence to take bodies from
the ground after burial for dissecting purposes, unless these
bodies are buried in Potter's field. Last spring, says the
Maryland Medical Journal, three men were arrested for
having in their possession bodies obtained from Bay
View, and being tried before Judge Fowler, at Town-
town, were convicted. The counsel for the defence
maintained that the Alms House burying ground was a
Potter's field, and hence was excepted by law, but Judge
Fowler did not entertain this opinion and the prisoners
were declared to be guilty. This decision was appealed
from, and after several trials the question was finally set-
tled by Chief Judge Yellott on Friday last, who said that
"any place where unclaimed paupers and strangers were
buried was a Potter's field," and the prisoners were ac-
quitted, after a confinement in jail of eleven months, in
one case.

THE OHIO SANITARY ASSOCIATION, at its meeting in
Columbus, February 14th, elected Dr. Wm. M. Beach,
of London, O., president, and Dr. Harvey Reed, of
Mansfield, secretary. After a successful and enthusiastic
session, the new organization adjourned to meet at Co-
lishus in February, 1885.

A BILL TO DEFINE THE TITLES OF MEDICAL OFFICERS
IN THE ARMY. A bill has been introduced into the U. S.
Senate (S. 1559), which aims to change certain titles.
The six (medical) colonels are to be called "assistant
surgeons-general," the senior officer being charged with
the duties of chief medical purveyor. The lieutenant-
colonels are to be styled "deputy surgeons-general."

THE TROUBLE IN THE ST. LOUIS COLLEGE OF PHY-
SICIANS AND SURGEONS, mention of which was made in
The Review of January 19th, has culminated in the
withdrawal of eight of the faculty. It will be remem-
bered that these eight professors sent in their resigna-
tions some time ago, but still continued lecturing, and
it was supposed they would do so until the end of the
session. It appears, however, that new grievances were
discovered, which resulted as above mentioned. The
students who passed resolutions pledging themselves to
leave the college with the seceding portion of the fac-
ulty have changed their minds, and concluded to remain
in the college.—The Medical Review.
THE MEDICAL RECORD.

273

March 8, 1884.

Debates of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, February 13, 1884.

GEORGE F. SHEPARD, M.D., PRESIDENT, IN THE CHAIR.

(Continued from p. 248.)

Dr. W. P. NORTHUP presented a specimen of

IMPERFORATE ANUS

removed from the body of a male child ten days old, inmate of the New York Foundling Asylum. The child was admitted to the house December 27th, aged twelve hours, and was sent out to wet-nurse the same day. It was rather small and probably premature. It remained with its nurse two days, when it was returned. The nurse reported that it nursed well, but vomited soon after it finished nursing, and further, that the child's bowels had not moved during its stay with her. On examination it was noticed that the abdomen was tensely distended and tympanitic, the skin dusky and in places livid, the superficial veins distended and very prominent.

December 31st.—Child four days old. Examined by Dr. O'Dwyer in consultation with the House Physician, Dr. Blodgett. Anal ring normal. On pushing the little finger through the grasp of the sphincter a cul-de-sac was met just within the sphincter. By gentle pressure the finger was pushed through this limiting membrane, when the finger came into a cavity bounded on the sides by a defined wall (the muscular portion of intestinal wall), above by a tense, fluctuating convex partition, which felt like the "bag of water" in a half dilated os uteri.

A sharp-pointed scissors was passed along the finger as a guide and a small opening made. This opening allowed a discharge of meconium. The opening was freely enlarged and a large quantity of meconium and gas discharged. From this time the child was bottle-fed. It gradually failed and died January 5, 1884.

On autopsy the intestine was found to be normal down to the rectum. Just above the internal sphincter the rectum ends in a cul-de-sac. This cul-de-sac is formed of mucous membrane only, the muscular portion of the gut continuing along in its normal course. So we have a cul-de-sac above the internal sphincter with its concavity up, another cul-de-sac just within the lower sphincter with its concavity down. Between these two is only loose connective tissue. It was into this cavity the finger of the operator first forced its way. The lower or external cul-de-sac is of muco-cutaneous tissue—no rectum tissue proper.

The wall of the rectum at its lowest portion is constricted, but no harm has been done to any adjacent organs.

The remainder of the record of autopsy is not pertinent to the specimen and is therefore omitted here.

GENERAL INTERSTITIAL INFLAMMATION.

Dr. A. JACOBI presented a series of specimens removed from the body of a child that died at Bellevue Hospital. They were accompanied by the following history, furnished by Dr. Jacob H. Frankenberg, Acting House Physician:

Emil L., fourteen months old, admitted to Bellevue Hospital February 2, 1884. Previous history of the child unknown. On admission child seems well developed for its age; bones are firm and resisting; the anterior fontanelle has almost completely closed; child is somewhat anemic; muscles rather flabby; child appears to be suffering pain, being very restless, uneasy, and feverish, and at times cries out without any provocation. The skin feels hot to the touch; temperature 103° F. per rectum; pulse 140 per minute, regular but very feeble; respirations 42 per minute, hurried, shallow, and jerky.

Physical examination reveals rude breathing at the right apex, heard best in front; over the scapular and sub-scapular regions, on the same side, subcerebral rales and small areas of rude breathing are heard. The cervical and bronchial glands on the right side are considerably enlarged. Deep fluctuation was made out on the right side of the neck.

February 3d.—Toward midnight yesterday the child's temperature sank to 99° F.; its pulse became less rapid; the breathing became calmer; it was less labile and feverish, and sank into a quiet sleep; it slept well all night and took its food nicely; it had three diarreal movements and had a slight cough.

February 4th.—Child's temperature varies a good deal; sometimes it is normal in the morning, sometimes in the evening, or it may rise at either time to 100° or 101° F. Pulse varies between 120 and 130 per minute and is rather feeble; the diaphoresis, which lasted during the first forty-eight hours after admission, has ceased. The child still coughs a little, otherwise it seems to be doing nicely; at times it utters a peculiar high-pitched shrill cry.

February 5th.—Child is continuing in the same manner as heretofore, eating and sleeping well; bowels move but once or twice; it has occurred to 100° or 101° F., and at one time it rose to 103° F., but remained elevated only for six hours, responding quickly to the use of gr. ii. of ac. salicyl. repeated three times at intervals of one hour. It still coughs now and then with an occasional shrill cry. Child's respirations are no longer labored nor are they so rapid, 31 per minute.

February 10th.—Child's temperature was normal all day yesterday, but toward evening the pulse became very rapid, mounting to 144 per minute. Its face and conjunctive became slightly icteric and its appearance somewhat drowsy, otherwise it was well; ate nicely during the night, and even this morning at nine o'clock it took all the food given to it, but appeared to be drowsy. The jaundice persisted in the same light form as yesterday. At about ten o'clock the child was inadvertently noticed by the nurse to become more restless. Its temperature was found to be 97 1/2° F., but its pulse was very rapid and exceedingly feeble, numbering over 150 per minute. Soon afterward it developed edema of the lungs and died at 12.30 P.M., notwithstanding the free use of stimulants, etc.

Autopsy.—The eyes and skin were of a slightly yellowish tinge. Neck: After removing the enlarged glands on the right side of neck an abscess was revealed which seemed to be entirely encapsulated; its outer wall was partly rough, being formed by a number of suppuring glands; the carotid sheath formed also a part of the outer wall; its inner wall was formed by the outer wall of the pharynx, oesophagus, larynx, and trachea; it extended from the base of the skull, immediately in front and to one side of the foramen magnum, to the pleura, being separated from the pleural cavity only by the parietal pleura. There seemed to be no opening leading from the abscess cavity elsewhere. The external fistulous opening could not be traced to the abscess cavity. The tracheal, bronchial, and mesenteric glands were all found enlarged, but none were found in a suppuring condition except the few above referred to.

The lungs: The left lung was tolerably normal; a small amount of hyperstasis and considerable emphysema at the apex. The upper lobe of the right lung was the seat of interstitial pneumonia. There was a good deal of new formation of interstitial tissue, and the air-cells were filled with the usual pneumonic products. The liver was enlarged, heavy, and showed a large number of little dots, part of which consisted of fat; most of the tissue, however, was a new interstitial growth. It was a cirrhotic and, in part, a fatty liver. Both of the kidneys were in a condition of interstitial nephritis, the left more
markedly than the right. The spleen seemed to have undergone the same interstitial change. There were quite a number of dark spots in the centre in which there had occurred hemorrhage. The wall of the lower portion of the small intestine was thickened; in a few places there were ulcerations. There was considerable swelling of Fyer's patches, a good deal of redness of the glandular and mucous tissue, and probably congestion of the submucous tissue. The colon and rectum were substantially normal. The brain was apparently normal. No gummatas were found in any part of the body. The process seemed to be a general interstitial inflammation. It had been impossible to obtain any information with reference to specific disease, but probably the true explanation of the interstitial change throughout the different organs of the body must be on the ground of hereditary syphilis. Gummatas, as a manifestation of syphilis, are not of so frequent occurrence in the viscera of infants as is general hyperplasia of tissue. There was no suspicion of tuberculosis.

On motion, the specimens were referred to the Committee on Microscopy.

Dr. J. Lewis Smith remarked that pharyngeal abscess is more common in New York among infants than is generally supposed. It is very frequently overlooked, and the cases are supposed to be those of chronic laryngitis or pharyngitis from some other cause.

Cancer of the cesophagus and stomach.

Dr. Beverley Robinson presented a specimen, with the following history furnished by Dr. Wm. H. Sherman, Junior Assistant at St. Luke's Hospital. John D., forty-two years of age, and a hosieller, was admitted January 2, 1884. His family history was good. He had a very debilitated constitution five years ago, and had been subject since to ulcerated sore throat. The patient had been suffering from a cough with profuse muco-purulent expectoration for the past six months. He had been accustomed to vomit frequently. He had considerable dyspepsia, and stated that he had lost some flesh.

Physical examination revealed asphoany and a metallic ring during cough over the eighth left intercostal space in the back; there was flatness on percussion, extending from two inches above the angle of the left scapula to the base of the left lung and into the axilla, where it reached the seventh intercostal space. Airy cough and breathing were heard over the left base posteriorly and in the left axilla. Thoracic vesicles were present over a good part of the right side and on the lower part of the chest on the left side. Over the upper part of the left lung there were pleuritic and subcutaneous rales, and the respiration was feeble. On the right side respiration was feeble and, in certain areas, blowing in character.

On January 4th a puncture was made posteriorly in the ninth space on the left side and three ounces of a clear, straw-colored fluid withdrawn. The above signs still continued after the withdrawal of the fluid, and, in addition, some rales were present. A needle introduced in the eighth space over the seat of asphyactic breathing gave a negative result. On January 5th the asphyxic breathing could not be heard in the axilla. The patient complained for the first time of some difficulty in deglutition, stating that he found it necessary to wash all his food down with large amounts of water. January 7th tinking was heard over the supposed cavity. January 18th patient had an attack of severe dyspepsia, lasting for about an hour. During the evening of the 20th the patient was again seized with attacks of severe dyspepsia, during one of which a tonic contraction of all his muscles was present. Dehiscence occurred on the morning of the 21st.

Neither vomitting nor regurgitation of food were observed while the patient was in the hospital.

Post-mortem examination.—There were about three ounces of fluid in each pleural cavity, and five ounces of reddish serum in the pericardial sac. The right lung was congested and edematous, and the bronchi contained mucus and pus. The anterior portion of the lower lobe and the entire upper lobe of the left lung were well supplied with air and were moderately oedematus. The posterior part of the lower lobe of this lung was hepatised and mottled in color. At the lower end of the cesophagus there was a nodular growth, whitish in color on section, two inches in length and one-half an inch in thickness and about the same breadth, involving partly the stomach and partly the cesophagus. Above this there was a mass of similar composition involving the entire circumference of the cesophagus, excepting a small band about one-fourth of an inch in width, and which was firmly adherent to the aorta, and was in close proximity to the vessels and bronchial tube, thus forming the bronchus of the left lung. This latter mass commenced one inch above the former and was about five inches in length. It was whitish in color and in places quite firm, elsewhere very brittle. The mesentric glands were enlarged.

The microscopical examination, made by Dr. F. Ferguson, showed epithelial cells abundant, arranged within alveoli limited by narrow fibrous walls. The epithelial cells were large, cuboidal in shape for the most part, and the fibrous stroma was scanty. The parts adjacent to the developing growth contained extensive areas of small round cells of inflammatory origin.

Remarks.—The patient, whose history I have read, was an internee, one during last year when I first examined him was that he had an encysted or limited empyema on the left side, situated between the upper and lower lobes, and communicating with a large bronchus. I subsequently was of opinion that I had to do with a very large pulmonary cavity and a much-thickened pleura covering it. Personally, I had not believed in the existence of a solid tumor. My diagnosis was based upon the flatness, amorphic cough and breathing, profuse purulent expectoration, duration and general symptoms of the disease. I made two negative punctures over the seat of what I believed to be a purulent cavity.

With the signs presented during the life of my patient, I still consider my erroneous diagnosis to be justified by the results of auscultation and percussion. After death the amorphic cough and breathing were possibly accounted for by the presence of a cavity in the tumor itself communicating with the cesophagus, or else by a relatively increased calibre of bronchus below the level of pressure by tumor. No orifice leading into a bronchus of any size was discovered, and, therefore, that it is not absolutely essential for the production of the type of breathing, via, amorphic, which I have mentioned to have an intra- or extra-pulmonary cavity communicating with a bronchus.

"The mucous rales, heard more than once, must have taken place in the bronchial tubes. It is a singular fact that this patient complained only for the first time of difficult deglutition on January 4th, or two weeks before his death. He did not have a single attack of vomiting during the three weeks he was in the hospital. With such involvement of the cesophagus and stomach by the malignant growth as is here shown, this fact is certainly remarkable."

Dr. John A. Wyeth exhibited

An instrument for dividing bones in Excisions, a description of which will appear in a future number. The Society went into executive session.

The dose of Nitro-Glycerine recommended by Dr. Roberts Barlowith in albuminuria is mil. of the one per cent. solution three times a day, or every three or four hours. It is to be used after the subsidence of the acute symptoms. The chloride of gold and sodium is given in the subacute and chronic stage in doses of gr. 1 twice daily to gr. 1/4.
NEW YORK ACADEMY OF MEDICINE.
SECTION IN OBSTETRICS, AND DISEASES OF
WOMEN AND CHILDREN.
Stated Meeting, February 28, 1884.
ALEXANDER S. HUNTER, M.D., CHAIRMAN.

DIPHTHERITIC CROUP, ITS TREATMENT BY SOLVENT INHALATIONS AND TRACHEOTOMY.

Dr. J. LEWIS SMITH read a paper on the above subject, in which he first directed attention to the etiology and the anatomical characters of the disease. In New York the percentage of cases in which the larynx has been involved has been large. Speaking of the exudation, Dr. Smith said that above the vocal cords it was intimately incorporated with the mucous membrane; while below the vocal cords it lies simply in contact with the mucous membrane. This fact had an important bearing on the question of tracheotomy.

Diphtheritic croup, when left to itself, almost never abates, but extends into the larynx and trachea, and produces distressing and dangerous symptoms.

Dr. Smith believes that there is a membranous croup which is a local disease, and does not partake of the nature of diphtheria, although its occurrence is rare, and physicians in rural regions may not see more than one or two cases during the course of a long practice.

With regard to treatment, inhalations in diphtheritic croup might give better results if the disease did not progress so rapidly. As a general rule, if no amelioration of symptoms occurred within four days, the case would terminate fatally. According to his experience and observation, about one in eight recover under treatment by inhalation.

With regard to tracheotomy, the author of the paper gave a series of statistics from which it appeared that from twelve to thirty-nine per cent. had been saved by the operation, and he believed that, under improved methods of operating, and at the present time, the disease evidently having changed its character within the last three or four years, it might be expected to save one in three by tracheotomy.

The solvent which he recommended was lime-water with a small quantity of caustic potassa; one part of liquor potassa to fifty of lime-water; and the lime-water should contain an excess of lime so as to be a trifle turbid. He recommended glass atomizers he regarded as inefficient; a metallic point which will carry a large column of spray should be used.

Dr. Smith thought that, when the cough increased in harshness, the hoarseness increased, and the voice grew feeble, the patient became restless, and the respiration labored, tracheotomy should be performed without delay. Emetics are not advisable as an adjuvant in the treatment; they will only hasten a fatal termination. If the case steadily progressed unfavorably, the physician should not wait until the patient is moribund before resorting to tracheotomy.

At the conclusion of his paper Dr. Smith read a letter from Dr. John A. Wyeth, who approved of performing tracheotomy without closing the wound.

Dr. S. M. ROBERTS thought that tracheotomy was a simple operation, and that it should be performed as soon as the patient began to have labored respiration. The dangers in diphtheria were from blood-poisoning, membranous tracheitis and bronchitis, broncho-pneumonia and exhaustion. The condition of the patient with reference to these matters determined the decision as to whether or not the operation should be performed. If blood-poisoning was already profound, if broncho-pneumonia had developed, etc., the operation would not save the life of the patient. Tracheotomy probably increased the liability to the development of broncho-pneumonia, and therefore, when he found high temperature with rales in the chest, he regarded the condition as one which contra-indicated the operation. He had seen five recoveries under treatment by packing the neck over the larynx with ice, after it was evident the vocal cords had been involved by the membrane.

Dr. C. A. LEALE thought tracheotomy should be performed only as the last resort, and for the reason that he had seen several cases in which the operation was refused, and yet the patients recovered. There are cases, however, in which tracheotomy positively cures the patient. He regarded it not as a simple but as a difficult operation to perform, and also one dangerous to the operator.

Dr. JORL. FOSTER referred to a case in which cure was effected, apparently, by inhalations of lime-water continued for twelve days.

Dr. STICKLES urged the necessity of treating apparently trivial cases of sore throat with care, especially when diphtheria was prevailing.

Dr. F. LANGE regarded tracheotomy as a symptomatic remedy. He did not believe that either the progress or the cause of the disease was influenced by the operation. He had operated in thirty-two cases, with eleven recoveries, but he believed that he did nothing more for his patients who recovered than merely to get them over a difficult point at the time the operation was performed. The danger from extension of the disease downward, he thought, had not been averted by tracheotomy. Nor, on the other hand, did he believe that local applications had done any good. The operation certainly added to the danger in the case.

If we could get along without the canula, it would be very good. He had tried to get along without it, but had abandoned the plan. He thought a good-fitting canula did no special harm—it should not fit closely—at least it gave safety.

He preferred to perform the operation above the isthmus, because at that point the trachea was more superficial than lower down, and prominent blood-vessels were avoided. He always made a large opening in the trachea, and never refused the operation so long as the changes in the lungs were certainly fatal. A moist air was favorable, but an atmosphere carrying any medicament, he thought, did not exert any specially beneficial influence on the diphtheritic patient.

Dr. Smith, in closing the discussion for the evening, referred especially to the change in the character of the disease which had occurred within the last three or four years, and that tracheotomy performed now gives better results than it did formerly.

The further consideration of the subject was postponed until the stated meeting, March 27, 1884, when the discussion will be opened by Dr. John H. Ripley.

AN ANODYNE MIXTURE WITHOUT OPium.—Dr. A. P. Meyler, of this city, sends us a formula somewhat resembling that of chlorodyne, and writes: "It has given me no little anxiety to find a suitable anodyne for patients cured of the opium habit. In attacks of intestinal colic or neuralgia, to which they are subject, any preparation containing morphia is necessarily excluded, since it would at once bring back the old habit. The following formula is the result of various experiments, and has been used with good results in my cases. Perhaps its publication may lead others to relate their experience likewise:

OUR LONDON LETTER.

(From our Special Correspondents.)

ALCOHOLIC POISONING—CHOLERA—DRS. BALFOUR—SEWAGE IN THE THAMES.

London, February 16, 1884.

At the meeting of the Medico-Chirurgical Society on the 12th inst., an interesting paper by Dr. Broadbent on "Alcoholic Poisoning" was read. Several cases were referred to by Dr. Broadbent in which alcohol having been taken in unusual excess paralysis came on, increased rapidly, and terminated fatally. In one case seen by Dr. Broadbent, the patient (a dipsomaniac who had never had decided symptoms of delirium tremens) had been failing in mental power for some months, and the arms had been weak for a fortnight, but there had been no marked loss of power in the hands till within a few days of the date when the patient was first seen by Dr. B. The paralysis was then chiefly manifested in the extensors of the fingers, causing wrist-drop. The flexors, though, were weak. The trunk muscles were also feeble, and the patient could not stand alone, though he could move his legs freely in bed. Knee- jerk lost; sole reflex marked; sensation unimpaired; sphincters not affected. The hands were pale, purple, and puffy, and the feet swelled when hanging down. The paralysis rapidly increased in extent and severity. The respiratory muscles became implicated and death from asphyxia occurred eight days after the consultation with Dr. B. This patient had become addicted to alcohol in early manhood, and had gradually become inert and sedentary in his habits, spending most of his time in bed, in reading, and in drinking port. Several other cases were referred to, in which the patients were sedentary in their mode of life, and the majority of them were females. Dr. Broadbent considered that the determining cause of the disease attacking the spinal cord was the want of exercise. The disease most resembled acute ascending spinal paralysis, differing from it chiefly in the order in which the different parts of the cord were attacked. The wrist-drop at an early period was highly characteristic.

At the same meeting some discussion took place on cholera and its relation to micro-organisms. The discussion was occasioned by the fact of Professor Marshall, the president, having received a series of microscopical preparations from Dr. Straus of Paris. Eight were sections of small intestine and two were preparations of rice-water stools of cholera patients. The latter contained numberless organisms of every kind, but none very characteristic. A committee is to be appointed to examine and report on the specimens. In the discussion which followed, most of the speakers declared themselves non-believers in the contagiousness of cholera. The opposite side, in fact, found no defender.

I have to chronicle the death of Dr. Balfour, lately Professor of Botany in the University of Edinburgh. His son, Dr. Bayley Balfour, has just been appointed professor of the same subject in the University of Oxford. The University of Edinburgh has been noteworthy in furnishing professors for other universities and colleges. As a set-off it may be observed that one of its most distinguished professors at the present time received his medical education in one of the London hospitals and graduated at the London University.

The first report of the Royal Commission on the Metropolitan Sewage Discharge has just appeared and is exciting considerable interest. In it the commissioners particularly acknowledge the loss of a long held patent to everybody viz.: that the discharge into the Thames, even so low down the river as the present outfalls, of such a bulk of raw unfiltered sewage as that proceeding from the area included within the Metropolitan sewerage system is a real nuisance. It is obviously one likely to increase year by year. It is, however, easier to find fault with the present system than to remedy it, considering that the sewage of a population numbering nearly five millions is to be dealt with, and the commissioners reserve their remedial measures for a future report. The commissioners might turn their attention with advantage to the question of preventing pollution of the river above the points at which the water companies have their intake. I believe I am correct in stating that a good deal of river pollution still goes on some miles up the Thames from houses and villages on its banks.

A SUGGESTION TO REMEDY DISPENSARY ABUSES.

To THE EDITOR OF THE MEDICAL RECORD.

Sir: The discussion of the subject of free medical aid to the poor at dispensaries seems now in order, and the evil of giving too indiscriminately calls loudly for a remedy.

The free discussion through the medium of the medical journals of other evils relating to our profession has, in many cases, resulted so favorably as to lead to the hope that in the near future this misplaced charity may be remedied, and to this end I would offer the following suggestion: That a physician be appointed to each dispensary and institution where the poor are treated gratis, whose duty would be to investigate the case of every applicant.

Whenever any doubt existed as to the worthiness of the applicant the physician should visit the residence of such an one and more fully satisfy himself of the financial condition of the suspected one.

A practical guard of this kind would, I think, carry with it a healthy moral effect on the applicants for charity, and, when once established, be productive of preventing impostors from even making application at the dispensaries.

These physicians should receive a salary paid out of the funds of the city, which would have the effect of making them independent of the dispensaries and uninterested in the supply of material for clinical teaching, which of itself encourages the abuse of medical aid.

The question of the expense of an extra salaried officer to each of these institutions may be met at the outset by the fact that a large saving could be effected in the drug department, probably equalizing, if not exceeding, the salary of the extra physicians. Truly yours,

J. A. MECK, M.D.

30 West Twenty-fifth Street.

THE VAGINAL DOUCHE AFTER LABOR BELIEVED TO BE A NEW MISTAKE—THE STRICT HORIZONTAL POSITION, AN OLD ONE—SOME PLAIN AND COMMON-SENSE RULES.

To THE EDITOR OF THE MEDICAL RECORD.

Sir: Having noticed the articles recommending the medicated vaginal douche after labor as a preventive of puerperal fever, and knowing how grasping Americans are for anything new, would it not be wise to give the profession some statistics upon the subject, for and against; also a collection of the experiences of the profession at large?

I, for one, can state that during a general practice of nine years I have never recommended the use of the douche, medicated or otherwise, in such cases, and I have never had a single case of puerperal fever in one of my patients.

I have had cases of laceration of the cervix and rupture of the perineum, and I would no more think of
recommending the medicated or any other douche in those cases to prevent fever, than I would recommend the opening of an incised wound for the same purpose.

The preventives which I have relied upon are: 1. Patient to rise to a sitting position two or three times a day to empty bladder and rectum. 2. Take quinine sulph. fifteen to twenty grains a day in five-grain doses, for six days, or longer if the temperature indicate the slightest fever.

I am well aware of the fact that many practitioners will hold up their hands in horror at the idea of allowing, nay, in instructing a woman to rise from her bed to that stool immediately following labor; and, in fact, discard the bed-pan altogether. I am fully aware of the grave dangers pictured to the student in the lecture-room, and in the many works upon the subject; and for that reason alone I am emboldened to give the following:

When I graduated, in 1875, an old sage in the profession advised me as follows: "My boy," said he, "I am an old man; I have practised over fifty years, and, as you are aware, have been very successful. In regard to your labor cases, I would give you the following advice: First, as you intend practising in the city, make a habit of leaving your forces at your office; for if you ever return, you will always have ample time to send for them, and your not having them with you may save some woman much trouble. Second, do not examine your patient much or often. See that things are right, and then let nature manage the case. Third, instruct your patient when she desires to empty bladder or rectum, to have her night-glass conveniently placed near the bed in a chair, and while supporting the body with her hands, to rise carefully from the bed to the stool; and to return in the same way. Her rising will allow all clots, fragments of placenta, etc., to pass from the vagina, and you will be surprised to see how few cases of puerperal fever you will be troubled with. As for its bringing on hemorrhages, etc., that is all bosh. Let your patients keep the outside of their bodies clean, and attend to the calls of nature in a common-sense way, and depend upon nature to keep the inside all right, and you will be surprised at your success in this line of practice." I have followed the above advice to the letter, and am glad to say have never lost a single case, nor have I had any puerperal fever to contend with.

I believe that nothing can be more important in this line of practice is to keep the vagina of the lying-in woman as though it were a sealed room, keeping out of it everything—air, water, fingers, and instruments—for by their interference, I feel satisfied, could we have careful unbiased statistics, we would find that they, with the unchanged horizontal position, produce more cases of puerperal fever than they prevent. Respectfully,
A. E. Dugas, M.D.
Augusta, Ga.

THE COLLECTIVE INVESTIGATION OF DISEASE—SUGGESTIONS ON THE COLLECTION OF FACTS REGARDING INFECTION AND THE EARLY PHASES OF VENEREAL DISEASES.

To the Editor of The Medical Record.

Sir: Attention has recently been called to a subject—the collective investigation of disease—which I have for many years past regarded as the key-note to all prophylaxis and intelligent treatment of disease. To establish a system of this character it will, in my judgment, be necessary to start with subjects, or questions, of a practical nature. I know of none of more general interest and susceptible of easier accomplishment than that of venereal diseases. I suggested and advocated this plan eleven years ago, in an article on "The Treatment of Syphilis discussed at the Medical Congress at Lyons, with Remarks," published in the American Journal of Syphilology and Dermatology, April issue, 1873. I was ten years "in advance of the times." As the subject is still a good one and the hour seems more propitious, may I not claim a little space to repeat my propostions to your many readers, with the hope now of bringing the subject the attention I think it really deserves?

"It is well known that comparatively little attention has been paid to the collection of statistics of a trustworthy character of the phenomena of syphilis. This may be accounted for from the fact that only a very small proportion of those who suffer from the disease are under my care. To the person who gains by clinical observation. It cannot, of course, be expected that every one who treats venereal diseases will take any special pains to record their observations. Many who might be induced to do so are deterred from want of time, the ability, and other causes, which could be overcome if a simple style of record were prepared in which the main features of the disease could be noted in a printed form of blank prepared for the purpose.

"If any branch of medicine is to be put on a sound basis, it can only be accomplished in the manner, and on the same principles, pursued in other departments of science. Here it has been too much the habit to collect statistics for the purpose of surmounting a difficulty—too seldom to throw broad rays of light on our knowledge of disease. This has certainly not been creditable to us as scientific observers. Statistics of venereal diseases will not serve any scientific purpose until a system is adopted by which every practitioner may be enabled to register in a certain definite form a full and distinct account of every case of venereal infection coming under his care, and which may be placed at the disposal of those who are devoting their attention to the mysterious problems of the evolution of syphilis. This will doubtless seem a very difficult task. It is, but the difficulties may be overcome in the manner we suggest: to prepare blanks of a uniform size, with printed suggestions calling for full answers on all the special points and features of interest in the history of syphilistics. To those in general practice we must look for assistance in the advancement of our knowledge of special diseases." I will gladly contribute the results of my own experience, or aid any one with any further information coming within the range of my own observations.

Morris H. Henry, M.D.
55, Fifth Avenue,
New York, March 1, 1884.

THE USE OF PEROXIDE OF HYDROGEN IN DENTAL SURGERY.

To the Editor of The Medical Record.

Sir: The letter of Dr. R. W. Steyer on page 81 of The Medical Record, concerning the uses of peroxide of hydrogen in the treatment of venereal diseases, also contains a brief reference to its use in dental surgery as a mouth wash. The attention of physicians and surgeons is hereby directed to it, and its efficiency as a thorough cleanser of the oral cavity when that cavity needs such cleansing; but it is not as a mouth wash alone that it is used in dental surgery. Practitioners of dentistry are using it daily for the bleaching of pulpless (discolored) teeth, in the treatment of alveolar abscesses, and as an injection into the pockets of the so-called Rigg's disease, or pyorrhoea alveolaris. As a germicide for the destruction of the micrococci found in the pus of pyorrhoea it is unrivalled. Your correspondent has used it as an injection in abscess of the antrum, with most gratifying results. Its modus operandi seems to be the same as the use of H2O2, brought in contact with pus, the extra O is liberated so rapidly that the H and S of the tissues immediately

1 For a more extended account of the uses of H2O2 in dental surgery, see the Dental Cosmos, October, 1885-83; also the Independent Practitioner, February and March, 1883, etc.
The above cut represents such an instrument as I have had made by Mr. W. F. Ford, of Caswell, Hazard & Co., and used with great satisfaction. I have used it in the operation of staphylorraphy in very young children, and it serves equally well in the adult. The tooth-cups, A, A, are deep and long enough to embrace two molars. There is placed in them a small quantity of soft rubber, or, what has proved more useful to me, gutta-percha, as it can be warmed and the teeth and gums embedded in it. This gives a firm bearing and is very secure. The sliding-ring B holds it very firm against the teeth, and in an instant can be released by sliding it to the centre of the shaft, which lies close upon the cheek. By means of the handle the head of the patient can be controlled by an assistant.

INSANITY IN AUSTRIA.—There are in Austria 21 public and 5 private insane asylums, containing a population of 6,200 persons, who are cared for at a yearly cost of 1,650,000 florins. The largest asylum is at Prague, and contains 1,332 beds; that at Vienna contains 553 beds. Most of the asylums contain from 300 to 400 beds. About 16,168 insane persons are treated in their homes. The entire number of insane is 25,038, of whom 13,669 are males; 11,369 females. Of these cases 11,068 are between the ages of 25 and 40 years.
degrees the charge to the graduates was delivered by Dr. Roswell Park, of the faculty. Reviewing the history of the college, and paying a word of tribute to each of the illustrious names found in its history, the roll of those who had been its teachers in the past, he urged upon each member of the class to do his utmost to maintain and to add to the name of his alma mater. Then followed the address to the Alumni Association, by the Hon. James O. Putnam, of this city. This address was the centre of interest in the exercises of the evening. Beautiful in its conceptions and matured in its criticism, the role of the physician in the future, it taught us to forget the narrow lines of systems and of theories, and to fix the attention steadily upon the ultimate aim of our calling. Listening to it you believed, if you ever doubted, in the grandeur of the medical profession. It was an incentive to a renewal of our efforts for the elevation of the science and art of medicine. The meeting of the Alumni, which occurred during the day, was as interesting as any in the history of the Association. The scholarly and instructive address of the President, Dr. E. N. Brush, of Utica, was an eloquent plea for a higher medical culture and better means of education. We quote one passage as follows: "Let us, then, as practitioners demand of young men preparing for professional life a foundation upon which it may be tested by a preliminary examination before admission to a medical college. Let us further urge upon medical colleges an extension of the curriculum and time of study, and finally let us labor for the day when medical schools shall be thoroughly endowed, well equipped with libraries and laboratories, and where the highest scientific attainments and longest and largest experience shall find relief from active work of professional life in collegiate positions." The following papers were then read: "Energy of Nerve and Brain" (Illustrated), Professor W. H. Pitt, M.D., Buffalo; "Operations for the Radical Cure of Hernia and their Results," Professor Roswell Park, M.D.; "Defects in House Lines and Plumbing, with the Proper Remedies" (Illustrated), Professor W. Sheehan, M.D., Rochester. The officers then elected for the ensuing year were: Dr. E. C. W. O'Brien, of Buffalo, President; Dr. Conrad Diehl, of Buffalo, First Vice-President; Dr. D. W. Harrington, of Buffalo, Second Vice-President; Dr. Mary B. Mendenhall, of Buffalo, Third Vice-President; Dr. John D. Sheehan, of Rochester, Fourth Vice-President; Dr. Theo. H. Boysen, of Buffalo, Fifth Vice-President; Dr. Henry Lapp, of Clarence, Trustee; Dr. A. M. Barker, of Buffalo, Secretary; Dr. E. C. W. O'Brien (ex-officio), Dr. Charles Carey (ex-officio), Dr. C. A. King, Dr. J. W. Putnam, Dr. J. H. Potter, Executive Committee; Roswell Park, Herman Mynter, J. F. King, E. T. Dorland, Honorary Members.

The Use of the Bromide Salts for Abdominal Neuroses.—Dr. J. K. Spender, of Bath, England, writes to the British Medical Journal upon the above subject. He says: "There is so strong a bond of therapeutic association between the bromides and the nervous troubles of head and chest, that we are apt to forget how useful the same drugs may be for sundry disturbances of the digestive organs; and yet all the physiological analogies of the subject would lend support to this doctrine. No one claims for the potassic and sodic bromides that they can clear away heterologous exudation, and mend damaged textures. But those of us who are still old-fashioned enough to believe in functional derangements, or dynamic force temporarily perturbed, can easily understand that there are certain aberrations of the cerebro-spinal system which, being of the same kind wherever they are situated, may be expected to yield to the same medicines. For an elderly woman who lives a sedentary life, often rather diarrhoea, I prescribed a few years ago some ordinary astrigent remedies, with minute doses of opium, to be taken according to her needs. But for another malady, sleeplessness, I gave occasionally moderate quantities of bromide of potassium. She discovered, however, that the latter remedy did her diarrhoea more good. For anything else, she said, in water, and never when at bedtime, the next day passed without any alvine looseness. Fourteen years ago Dr. J. Waring Curran recommended potassic bromide for the vomiting of pregnancy; but its real value could not be determined, as other things were combined with it (Medical Press and Circular, July 14, 1865). But I have given the medicine in its pure form, hourly or even half-hourly intervals; and he records the cessation of vomiting, the arrest of cramp, and the speedy return of warmth and color to the previously cold and livid surface. He tells us that the medicine was tried fairly, both in the Leith and Edinburgh Cholera Hospitals, and that its use has been uniformly favorable. It is the result of experience. It is to be hoped better fortified against the most painful and mortal of all abdominal neuromes. Lastly, I may glance at the use of the bromides in the treatment of saccharine diabetes. Here again Dr. Begbie started a line of therapeutic inquiry which has been successfully worked by other practitioners; and at this moment I have under my care a lady of between fifty and sixty years of age, whose special diabetic symptoms are clearly kept much in abeyance by a large dose of bromide of ammonium every night. Would this illustrate what has been called the 'alternative and absorbent effects' of the bromides on the liver?"

Tyndall's Theory of Explaining the Immunity Obtained against a Second Attack of Contagious Disease.—Professor Tyndall, in the Pall Mall Gazette, discusses the above subject in the following ingenious manner: One of the most extraordinary and unaccountable experiences in medicine was the immunity secured by a single attack of a communicable disease against future attacks of the same malady. Small-pox, typhoid, or fever, meningitis, for example, might, it is true, occur once in the lifetime of the individual, the successful passage through the disorder apparently rendering the body invulnerable. Reasoning from analogy, I have ventured to express the opinion that the rarity of second attacks of communicable disease was due to the removal from the system, by the first parasitic crop, of some ingredient necessary to the growth and propagation of the parasite. The cultivation of micro-organisms, which is now everywhere carried on, enables us to realize the smallness of the change which in many cases suffices to convert a highly nutritive liquid into one incapable of supporting microscopical life. Various important essays on this subject have been recently published in the Revue Scientifique. M. Boulys there draws attention to the results obtained by M. Raulin in the cultivation of the microscopic plant named Aspergillus niger. The omission of potash from Raulin's liquid suffices to make the produce fail to one twenty-fifth of the amount collected when potash is present. The addition of an infinitesimal amount of a substance iminal to the life of a plant is attended with still more striking results. For example, one part in sixteen hundred thousand of nitrate of silver added to the liquid entirely stops the growth of the plant. And now we come to the important application of this fact which has been indicated by Dr. Duclaux. It is connected with 'benign or harmless parasite—living contagium'—capable of self-multiplication in the human blood, and of so altering the constitution of that liquid as to produce death; then, the
introduction into the blood of a man weighing sixty kilogrammes of five milligrammes of the nitrate of silver would insure, if not the total effacement of this contagium, at all events the neutralization of its power to destroy life. An index finger here points out to us the direction which physiological experiment is likely to take in the future. In anticipation of the assault of infective organisms, the experimenter will try to introduce into the body substances which, though small in amount, shall so affect the blood and tissues as to render them unfit for the development of the contagium. And subsequent to the assault of the parasite he will seek to introduce substances which shall effectually stop its multiplication. There are the strongest grounds for hope that in the case of infective diseases generally such protective substance will be found.

Chloroform Narcosis during Sleep.—Dr. E. C. Brush, Surgeon Ohio Central Railroad, Cornings, O., writes: "The numerous articles published in the Medical Record during the past few months in regard to chloroform narcosis during sleep have brought out considerable testimony for and against its practicability. Seeing is believing, and as I have seen chloroform narcosis produced during sleep, I wish to add my testimony in its favor. I do not, by any means, claim that every one can accomplish this end, but know that it requires skill and experience in administering the drug, and with others the results would be, in my experience, unpromising. Serious doubts exist in my mind as to its being successfully used for criminal purposes by criminals, unless the administrator is an expert in its use. It is true that it might be, but the chances are largely against it. I was present and witnessed the experiments by Dr. Haldeman in the Ohio Penitentiary. Being the officer in charge of the hospital at that time, I was surprised one night by Dr. Haldeman calling with some medical friends and announcing the purpose of their visit. The convicts were not expecting anything of the kind, and had anybody known of the proposed visit it would have been myself. Dr. Haldeman had purposely kept me in ignorance of his intended experiments, so as to insure that nothing of the kind could be expected. I can add nothing to Dr. Haldeman's report (Medical Record, June 2, 1883), but substantiate every word of it. The narcosis produced was profound, accompanied by stertorous breathing and a complete relaxation of the muscular systems in both subjects. Before seeing these experiments I was a doubting myself, but now firmly believe that properly administered chloroform narcosis can be produced during sleep, not always, but at least occasionally."

A Case of Infantile Spinal Paralysis with Cerebral Complication Excited by Intestinal Irritation.—Dr. G. H. Arton, of Winnipeg, Manitoba, writes: "A case recently occurring in my practice has seemed to me worthy of record, not so much as a scientific contribution as a curio, which might be of service to some who, like myself, have practiced only general practice. I was called a few months ago to see a child between four and five years of age, supposed by the parents to be suffering from worms. They had already administered some vermifuge supplied by a druggist, but the symptoms were steadily on the increase and no worms had appeared in the stools. These symptoms were a growing inability to use her legs properly and some peculiarity of temperament. When placed on her feet the child would fall down, and when supported and made to advance she would cross her legs and throw them about in an apparently purposeless manner. On my arrival I verified the statements of the parents, and in addition found some muscular weakness in the arms, tremulousness of hands, and inability to control the movements of the extremities. Her temperature was normal; respiration, if anything, subnormal; pulse hard, small, and rapid. The whole surface of the body seemed hypesthetic. Both pupils widely dilated and feebly responsive to a bright light. Bladder acted all right, and the mother assured me that the bowels were regular. She added that she never allowed the child to use the water-closet, but always a chamber, and that she attended to her herself, and knew she had a daily motion natural in character. There was no special spinal tenderness, and the abdomen presented no peculiarities. Reflexes could not be made out satisfactorily. There were occasional twitches, but nothing approaching痉挛s. Examination of urine, chemical and microscopic, afforded no light. I gave a dose of calomel. This did not operate at all, but produced certain indications of distress which led me to direct her mother to use an enema. To my surprise, the first enema of nearly a pint was retained. A second was returned scarcely stained, and now it was evident that there was some hitherto undiscovered bowel trouble. This added to the difficulty of diagnosis, and as no symptoms appeared pointing to anything but severe constipation, it was considered as connected with the nervous lesion, whatever that might be. In the meantime the patient grew worse; her speech was thick, and it was almost impossible to keep her awake a minute at a time. When she was awake she complained of abdominal pain, but it did not prevent her sleeping. She was conscious when awake, and her pupils were still small and did not react. Feeling now almost certain of my diagnosis (cerebral anæmia), I gave sulphate of morphia in one-half grain doses. In a short time I had the satisfaction of seeing a slight improvement in the general aspect of the case, and the patient passed with incalculable difficulty a hard lump of feces, about one inch in length and as large in diameter. Feeling assured that more scybala remained, I ordered ox-gall enemata, which brought away in all fifteen distinct lumps similar to the first. Improvement followed, and kept up. Gradually somnolence disappeared, and the arms and hands improved. In about a week the legs were almost entirely under control, although for a month afterward her gait was more like a child's beginning to walk. Her speech remained longer affected, and in fact this symptom has not quite disappeared at date. Her pupils recovered their action very early. Her bowels now act normally. In conclusion I would call attention, first, to the mother's statement as to the regularity of the child's bowels before I saw her; whereas she had been evidently constipated; second, to the fact that in this case depending on the constipation, while the books tell us that such constipation depends on cerebral anæmia, and we usually find symptoms of cerebral hyperæmia when such marked constipation exists."

Remarkable Recovery from a Severe Abdominal Wound without Antiseptic.—Dr. J. C. McMillan sends us the history of a man, an engineer, who had received a cut in the abdomen during a fracas. The cut was four inches long, near the umbilicus, and extended into the peritoneal cavity. The intestines were protruded, and the small intestine cut half through in one place. The patient had lain in the road for four hours before Dr. McMillan saw him, and the protruded bowels were covered with dirt. He was taken to a house, anesthetized, the intestines cleaned with lukewarm water, the small intestine sewn up with silk suture, and the abdominal wound closed. The patient was well and discharged in two weeks.

An Inquiry about Drug Farms.—Dr. Frank P. Hudnut, of Salem Centre, N. Y., inquires what kind of medicinal plan she could refer the following patient, on whom...
Sternberg, Geo. M., M.D., Major and Surgeon, U.S.A.

(Continued from p. 356.)

The difference is, in truth, considerably greater than this for no inconsiderable portion of the sickness from malarial diseases at the extreme northern stations is due to exposure in malarial localities farther south, and not to malarial of local origin. Regiments are occasionally changed from unhealthy southern stations to healthy northern stations, and detachments of recruits are frequently sent from depots located within the limits of active malarial development to the extreme northern stations where malarial of local origin is unknown or nearly so. Thus, at Fort Trumbull, Conn., which is not included in our list, we find that but two cases of malarial fever occurred in a garrison having a mean strength of 92 during the four years 1870–1874. But turning to a previous sanitary report we find that in 1869 there were thirty cases in a garrison of 76. Evidently those gentle- men who claim that there has been during the last few years a notable increase of malaria in Connecticut are mistaken. Our statistics show that at this point, at least, malarial diseases were far more prevalent in 1869 than during the four years following. But our statistics do not tell the whole truth. A remark attached to the sanitary report for 1869 states that the malarial diseases occurred in a company just from Fort Brown, Texas.

Let us now consider more in detail the facts relating to the prevalence of malarial diseases at some of the stations represented in our tables. It is somewhat surprising to find that at Fort Sullivan, Me., the most northern military station on the Atlantic seaboard, where the mean temperature for the months of July, August, and September, is but a trifle above 60° F., the amount of sickness from malarial diseases is greater than at any one of the three stations which follow it in our list. Our surprise is increased when we read that the island upon which Fort Sullivan is situated is a sterile mass of trap rock, about four miles long by two in breadth; that the fort is on an eminence about one hundred and fifty feet above tide-water, and that the drainage is perfect. Upon referring to the consolidated sick-report for each year, from which our ratio for the four years was obtained, we find that all of the cases reported, viz., five of remittent and seventeen of intermittent fever, occurred during the single year, 1872–73.

1 Read at the meeting of the American Public Health Association, Detroit, Mich., November 13, 1883.
producing numerous depressions, some round, some oblong, varying in size from thirty feet in diameter to as many yards. The result is that the whole country is dotted over with ponds from the surface drainage. Some of these ponds are clear, with a gravelly or clayey bottom and grassy borders; others are surrounded with trees, and filled up with bushes and rank grasses, and covered in summer with a green slime. It has been calculated that within a radius of a mile from Fort Hamilton there are at least sixty of these ponds. East of the fort, near the new battery, is a marsh of considerable extent, formed by the drainage of the higher land, and imperfectly separated by a bank of sand from the tide-water. The natural drainage is bad; the ground being hilly, the water collects in the hollows, forming ponds that have become filled up with rank vegetation, the depth of water continually varying, being filled during the winter and spring by rain and snow, and in the summer and autumn becoming so nearly dry as to expose almost the entire beds to the direct solar rays" ("Report on Hygiene of the U. S. Army," 1875, p. 41).

As accounting, in part at least, for the considerable amount of sickness from malarial diseases at Fort McHenry, Md., we quote from the report of the medical officer stationed at that post:

"A ground spoken of in reference to the officers' quarters, and which fronts northeast on the Patapsco, should be filled in, or some means devised to prevent the overflooding it is subject to, as it is a fruitful source of disease."

Although not included in our table, because not directly on the seaboard, we may mention here Fort Foot, Md., an exceptionally unhealthy post, situated upon the banks of the Potomac River, eight miles below Washington. The ratio per thousand of cases taken sick with malarial fevers is more than double that at Fort Hamilton, the average for four years being 1,449. The following remarks by the medical officer making this report explains the unusual amount of sickness in a satisfactory manner: "In the rear of the fort is an extensive ravine, running in a northerly direction until it gets within about five hundred yards of the river, when it flattens out into a large morass, loaded with all kinds of organic matter in every stage of decomposition, giving forth exhalations most prejudicial to the health of the garrison. Along the shore of the river this place assumes somewhat the form of a cataract, the stupendous force of the water, meeting in the stream, which, being driven over the marsh by the tide, remains until destroyed by time. This piece of ground is overflowed by every high tide, leaving in all directions stagnant pools. It is believed that the malarial diseases prevailing at the post are largely due to the action of the sun's rays upon this large surface of decomposing organic matter."

The comparative healthfulness of Fort Macon, Ga., which is nearly three degrees south of Fort Monroe, where the ratio is greater, is accounted for by its insular position and exposure to the pure breezes from the Atlantic. From the "Report on Hygiene" we learn that it occupies the extremity of an island which is a mere sand-bar. "The porosity of the soil and the slope of the sand render the natural drainage most effective. . . . It is most probable that what little miasm is experienced is wafted by northern winds from inland swamps."

Again we find an exceptionally good record at Savannah, Ga., which is two degrees farther south than the last-mentioned station. When we learn that the barracks occupy the central part of the city, and that the company quarters are in the upper story of a two-story and basement brick building, we shall have no difficulty in reconciling this comparative healthfulness with the general proposition that malarial fevers prevail more extensively in southernmost than in northern latitudes; or, in other words, that heat is one of the factors which is concerned in the evolution of malaria.

If, now, we compare our two tables, one with the other, we shall find, as a general rule, stations in the interior suffer more from malarial diseases than those in the same latitude upon the seaboard, and that this difference cannot be ascribed to a higher temperature. Thus, if we compare Fort McHenry, Md., with Fort Leavenworth, Kan., which is in nearly the same latitude, we find the ratio of sickness is greater at the last-mentioned station, while the mean temperature for the year is considerably less. But Fort McHenry is an unusually unhealthy post for the seaboard, and the differ difference is much more striking when we compare Fort Macon, N. C., or Charleston, S. C., with such a station as Jackson, Miss., which is in about the same latitude; or Baton Rouge, La., with Key West, Fla., which is six degrees farther south, and has a mean annual temperature more than ten degrees higher. We must note, however, that the summer temperature at Baton Rouge is a little above that at Key West. These comparisons serve to illustrate the fact that malaria is of telluric origin, and that a station facing the broad Atlantic has the advantage, other things being equal, over a station in the interior. But in the case of these two exceptionally unhealthy posts in the interior, there are no doubt special reasons to which the unusual amount of sickness from malarial diseases must be attributed, for we refer to in the report relating to Jackson, Miss., but as regards Baton Rouge we read: "The malarial diseases prevailing at the post are immediately due in great part to the tract of swamp bordering the northern edge of the reservation, and the continuance of winds from that quarter is accompanied by a marked increase in the number and intensity of the attacks."

It may be thought that I am wasting my time in attempting to prove, what is very generally recognized to be a fact, viz.: that heat is one of the factors essential to the development of malaria, and that the malarial poison is evolved most abundantly from marshes and undrained lands rich in organic material of vegetable origin, and that consequently we are justified in speaking of malaria as a marsh miasm and of the malarial fevers as paludal fevers. But it has seemed to me to be important before we enter upon a general discussion as to the nature of malaria, that the broad facts which are well established should be prominently brought to view, as these are sometimes lost sight of by writers and speakers. The following statement from the report of the Medical Department of the United States Navy is a place than is accorded to the vast accumulation of evidence in favor of these fundamental facts. Certainly all of these exceptions must be reconciled with any theory which proposes to explain the nature of malaria and the laws which govern its evolution. But it would be a step backward to put aside the positive knowledge which we have attained as regards certain of the conditions which are connected with its production, because we do not yet know all of these conditions. In speaking of malaria as a marsh poison, medical authors certainly do not intend to convey the idea that it is produced only in low, marshy places, for it is well known that malarial fevers may prevail upon superfi cially dry uplands and away from swamps."

It can hardly be questioned, then, that moisture is an important factor in the production of malaria, and I think a broad view of the facts justifies the belief that it is an essential factor; for, so far as I know, there is not the slightest evidence that malaria can be evolved in the entire absence of moisture. But we must not expect the prevalence of malarial diseases to bear a direct relation to the rainfall of a place, for moisture is, con-
fessedly, but one of several factors, and, moreover, an impervious subsoil may more than compensate for a scanty rainfall in producing the degree of saturation most favorable to the evolution of malaria. In studying the influence of moisture, the tables which I have arranged with reference to another question will not serve us materially, as the rainfall at a majority of the stations included in them is probably sufficient, other conditions being favorable, for an abundant evolution of malaria.

The Report which furnished the figures for these tables contains hitherto the ample data for an interesting and profitable study of this question. This study I cannot attempt to make at present, as my paper has already been extended to too great a length.

For the purpose of obtaining additional data relating to this and other questions connected with our subject, I addressed, in March last, the following communication to the Medical Directors of the Departments of Arizona and of Texas, and to several medical officers of the army who have served in these departments, whose personal observations I believed would prove valuable:

Dear Doctor—At the next meeting of the American Public Health Association, to be held in Detroit, about the first of November, the subject of 'malaria' will receive special attention. I have been requested by the Executive Committee to prepare a paper presenting the actual state of knowledge as regards the nature and origin of the malarial poison, and the etiology of the malarial fevers.

The generally accepted view that 'malaria' is essentially a swamp-poison, and that its evolution depends upon, or is associated with the decomposition of vegetable matter, under the influence of heat and moisture, has recently been called into question by intelligent physicians in the New England States, because of the apparently erratic course of the malarial poison during the past three or four years, has extended over regions previously healthy.

It is claimed by some of these gentlemen that the accepted theory of causation does not act for the phenomena observed in these newly invaded regions, inasmuch as malarial fevers, until quite recently, did not prevail in the damp lowlands, in certain sections of North America, where now malarial diseases are rife, not only in the valleys, but on the hill-sides and in localities remote from swamps.

In order to discuss the subject intelligently I desire to obtain as extensive data as possible, and it has occurred to me that the facts relating to the prevalence of malarial diseases in hot and dry climates, like those of Arizona and portions of Texas, would be especially valuable, as the line of demarcation between the river-bottoms and the dry uplands is often very sharply drawn.

A line officer who has spent much time in Arizona assures me that 'where there is no water there is no malaria'; and I am informed by a physician who knows the territory well, that in some of the desert tracts water may be found by digging a few feet. "

I will be greatly obliged if you can assist me in obtaining the data required, and shall be careful to duly acknowledge such information as I am able to use. Your personal observations, and those of the medical officers serving at posts in your department, will be highly prized.

Full information is requested with reference to the prevalence of malarial fevers in your immediate vicinity, or in other localities with which you are familiar. Please give detailed information as to the type of the prevailing diseases ascribed to 'malaria'; the season of greatest prevalence; the character and mode of life of the population affected; the topography of the malarial and non-malarial regions under observation, etc. I desire especially to know if your experience justifies the generalization (as applied to hot and dry regions), 'where there is no water there is no malaria.' Also, whether in apparently dry regions, where malaria prevails, water may not be found near the surface by digging. Evidence relating to the distance which malaria may be carried by the wind is desired. Do you know of any facts supporting the view that malarial poisoning may result from drinking surface-water in malarial localities? Where exposure to malarial influences has been brief, as in the case of soldiers habitually living in a healthy locality passing a single night in a malarious river bottom, it will be exceedingly interesting to know how soon the symptoms of malarial poisoning have been developed. In other words, facts relating to the period of incubation are desired. Facts relating to the prevalence of malarial diseases in previously healthy localities, as the result of irrigation, of cultivation of the virgin soil, of engineering operations, etc., are requested. Also facts relating to the influence of forests, of winds, of artificial or natural drainage, etc. Have any well-authenticated instances of paralysis from exposure in malarious localities, among the lower animals, come under your observation? If so, please give full particulars.

"Communications relating to this subject should be placed in my hands by September 1st. Sym pathetic and true statements, embodying data of value, will be appended to my paper with due credit to the author, and will doubtless be published in the next annual volume of the 'Transactions of the American Public Health Association.' Very respectfully, your obedient servant,

Geo. M. Sterberg,
Major and Surgeon, U.S.A."

In reply to my communication, Colonel Jos. R. Smith, Medical Director, Department of Texas, in a letter dated August 2d, makes some interesting statements, which make the liberty of quoting, and furnished me a valuable table, which I submit for consideration without remark, because of the already too great length of my paper.

He says:

I enclose herewith a table exhibiting the absolute and relative number of cases of periodic fever occurring among the white and colored troops, respectively, and at each military post in this department during the year ending June 30, 1883.

Table Exhibiting Prevalence of Periodic Fevers at Different Posts in the Department of Texas.

</table>

"From it you will see that the percentage of these diseases was more than three times as great among the white troops as among the colored troops. Where white and colored troops were serving side by side at the same post, almost an equal great difference is observed."
"During the year previous, viz., that ending June 30, 1882, the percentage of cases of periodic fever occurring among the white troops was more than four times the percentage of cases occurring among the colored troops. With the locality of these posts you will get a general way familiar, and speaking in a general way the periodic fevers have been most prevalent in garrisons located in the valley of the Rio Grande.

"I have never known cases of periodic fever logically attributable to drinking surface-water in so-called malarial regions. I have known periodic fevers to occur in men who had drank surface-water in such regions. At the same time others who drank the same water failed to suffer from the fever, and others who never drank the surface-water suffered from the attacks of the intermittents.

"An answer to your question as to the type of the prevailing diseases ascribed to malaria—season, character of population, etc., would require an essay. A physician now in my sphere of observation designates any disease of type to him unknown or obscure as "malaria." You will easily see how general, then, may be the type of diseases "ascribed" to malaria.

"Many years ago I reported to the Surgeon-General instances where intermittent forms prevailed in newly inhabited locations—where these intermittents gradually changed to a malaria, with high intermittent fevers which, when the thermal area then occupied the whole state, was called by General Grant, who was with me at that time, "the fever that the Indians got from us." These attacks were so rapidly upon the pen that it requires washing off every few minutes. A No. 2 'Faber' leaves no more trace upon paper than a piece of anthracite, and it is necessary to keep one immersed in water while using one that has been standing in water some time.

Concerning malarial diseases in dry localities, and the possibility of finding water there, I will only say that in very many places in Texas heretofore supposed to be dry—even in the Llano Estacados—water has been found by digging, and that not at very great depths."

Colonel J. Cooper McKee, Surgeon U. S. A., formerly Medical Director of the Department of Arkansas, has taken much pains to obtain for me the facts relating to this subject from解锁 any of the nearby malarious regions, and reports the following: At Camp Lowell, Arizona, before and after the introduction of a pure supply of water for drinking purposes at these posts. These facts are embodied in a paper which he has kindly prepared at my request.

The following table (No. 3) shows the meteorological conditions at the stations referred to in Dr. McKee's paper and at several other military stations in Arizona, and the average amount of sickness from malarial diseases during the four years 1870-1874.

A reference to this table shows that malarial diseases were least prevalent at Mojave and Yuma, the two stations having the highest temperature. This seems to be accounted for by the very small amount of rainfall at these

1 By an oversight no duplicate copy of this paper was received by the writer, who is therefore obliged to refer the readers of The Medical Record to the forthcoming volume of the Transactions of the American Public Health Association, in which Dr. McKee's interesting communication will doubtless be published in full.

stations. On the other hand, the rainfall during the months of July, August, and September at the other three stations in our list seems adequate for the production of malaria and we find that the amount of sickness ascribed to this disease is smaller.

With reference to Camp Mojave we read in the Report on Hygiene that "the climate is healthy, the winters pleasant, but the summers extremely hot. There is no rainy season, though thunder-showers are frequent in July and August. The annual rise of the Colorado takes place in June. The prevailing winds in the summer are from the south, and passing over the arid plains, the air is so heated that it scorches like that from an oven. The nights are as hot as the days, the temperature not varying in the slightest degree for hours—so that no one can sleep in a house, the whole garrison lying on the open plain endeavoring to catch the slightest breeze, the walls of the houses becoming so heated as to render the barracks unendurable." In regard to Yuma, we read: "The heat rapidly increases from the latter part of May, and in June, July, August, and September may be said to be intense. In the months of July and August (the rainy season in Sonora) clouds are seen passing to the northeast, accompanied with rain, thunder, and lightning; occasionally they reach the vicinity of Yuma, and are most refreshing. During the months of April, May, and June no rain falls; then, with the thermometer at 105°, the perspiration is scarcely seen upon the skin, and it becomes dry and harsh, the hair crispy. Furniture put together at the North and brought here falls to pieces; travelling chests gape at their seams, and a sole-leather trunk contracts so that with difficulty the tray can be lifted. The extreme dryness of the atmosphere is easy to see almost by daylight when droplets of water, so rapidly upon the pen that it requires washing off every few minutes. A No. 2 'Faber' leaves no more trace upon paper than a piece of anthracite, and it is necessary to keep one immersed in water while using one that has been standing in water some time.

The mercury gained the highest point last summer on the second day of July, when for two hours it stood at 114° in the shade. All metallic bodies were hot to the touch; my watch felt like a hot boiled egg in my pocket; the cords of my grass hammock were heated like wires. At such times, if the wind is from the south, the air is like that from the mouth of a furnace, hot and ovenish." This vivid description of the heat and dryness of the atmosphere of the southern parts of California and Arizona draws attention to the malarial germ which, born in the lagoons and rich bottom lands in the vicinity of the fort, sally forth in the still hours of the night to attack the unhappy garrison stretched upon their backs on the open parade-ground, should become shrivelled and desiccated germ-nunmies, incapable of doing mischief long before they enter the open mouths of the panting and helpless soldiers. But I am not writing a romance and must beg pardon for this little flight of imagination at the close of a paper which has dealt thus far in solid facts.

I am indebted to Captain Joseph K. Corson, Assistant Surgeon U. S. A., for the following communication relating to the prevalence of malarial diseases in Arizona, and especially at Fort Yuma, at which post Dr. Corson was stationed for a considerable time.

1 Jefferson Barracks, Mo., June, 1883.

"Dear Doctor,—In reply to yours of March 23d, I take pleasure in submitting the following, which will depend for its value upon a simple statement, unsupported by data:

"My service in Arizona and Lower California lasted four years and some months—four months at Whipple Barracks and the remainder of the time, with the exception of a month's field service, at Fort Yuma, Cal. Prescott is situated about five thousand feet above sea level, and the post is still higher. The only water is obtained from Granite Creek, which about half the year is a 'sunk river.' The water-supply is obtained from wells sunk in
March 15, 1884] THE MEDICAL RECORD. 285

the bed of this stream. The region is a comparatively fertile one for Arizona, and rains in the latter half of summer and early fall are frequent and heavy. My service there was from June to October, and malarial fevers, chiefly in a remittent form, prevailed to a considerable extent, both in town and post. There were certainly few of the characteristics of a malarial region in this locality. A mountain town, with excellent natural drainage and no swamps or other centres of decomposing vegetation, and a clear, bracing climate. For one-half the year there was no visible water, though this could be procured in abundance a few feet below the bed of the stream. At Fort Verde, forty miles from Prescott, situated in the valley of the Rio Verde, on fertile bottom lands, malaria prevailed so strongly as to necessitate its abandonment.

Yuma is situated at the junction of the Colorado and Gila Rivers, in the ultra hot and dry part of the continent, so far as rain is concerned, the annual average precipitation scarcely exceeding two inches. The Colorado River has the reputation of being free from malaria, and my experience in the field leads me to believe this to be true. It flows swiftly through a bottom remarkably free of small vegetation. The mining towns along its course for a hundred miles above Yuma I have had opportunity to know are remarkably healthy. The Gila, in the eastern half of the Territory, where rains are comparatively frequent, has the character of a highly malarious stream. It is a sluggish stream, with alluvial lands and raised banks, generally thickly underbrush. At Yuma, the back waters of the river in the summer leave large lagoons, which to some extent remain the year round and bound the town closely on one side. It is, in fact, about one-half surrounded by water. The fort, situated on a high granite knob, about one hundred and fifty feet above the bed of the river, is a comfortable place, there being a considerable part of the year surrounded by water, running and stagnant. The town is built in the former bed of the Gila, and water can be procured but a short distance below the surface, and many wells are sunk for this purpose. During the overflow, water is frequently backed up in the streets, and great ponds stagnate for months at the doors of the houses. During nearly four years I was in active practice in the town, and now in looking carefully over my visiting list, and from remembrance, I can recall few, if any, cases which could positively be attributed to marsh miasm, originating at that place. It was certainly markedly absent compared with other similar regions. If I had served at of late years, unless certain prevalent nervous symptoms should be very nearly referable to that cause. These, consisting of neuralgias, principally facial, it is the fashion in Arizona to attribute to malaria, but as it has generally been met with in my experience in persons addicted to the use of spirits, I have not been convinced of the truth of this theory.

Probably no region can surpass the Colorado Desert in the characteristics of heat and dryness. Water has been procured only at a great depth by artesian boring, and water for the locomotives is carried from the Colorado. The rainfall is extremely light, and vegetation to a great extent, absent. The population is naturally very light, being confined almost to the employees of the railroad, but for a year or more a placer discovery caused quite a large population to locate upon the desert. The sick from this settlement naturally came to Yuma, and I have the remembrance that it was a markedly healthy community, so far as endemic disease was concerned.

The experience here related, in its bearing on the theory of "no water, no malaria," seems conflicting; Certainly, Yuma possesses, in an exaggerated degree, all the factors which we suppose favorable for the development of swamp poison, and I can only account for the non-existence of malarial disease by the theory that, while marsh miasm exists there, as under similar conditions at other places, the exceptionally dry air has no carrying power, and that the human system is virtually insulated by it.

"I incline to the opinion that water is essential to the production of malaria, but that heat, water, and decomposing vegetation may all be present without the development of miasmatic disease I believe possible."

We remark, in conclusion, that this possibility cannot be denied, and that it is even supported by observed facts. But as there is, in all probability, another essential element in the equation, an unknown biological factor, we need not be surprised at these apparent exceptions. And we cannot expect to explain all of the phenomena relating to the evolution of the malarial poison until we have obtained some definite information as to the kind of vegetable decomposition upon which it depends, and as regards the life-history and conditions of development of the living ferraent, or ferment, which are concerned in this decomposition, the physiological changes which these micro-organisms may undergo in Nature's laboratory from changes in their environment, and the enemies with which they have to contend in the struggle for existence.

THE DANGERS OF AN UNSKILFUL OR CARELESS APPLICATION OF HEAT AND COLD TO THE SPINE.

By B. O. KINNEAR, M.D., BOSTON, MASS.

In the articles which I have already published in the Boston Medical and Surgical Journal, August, 1882, and May, 1883, I have endeavored to demonstrate the power of Dr. John Chapman's method by the results obtained, as well as by an explanation of the manner in which the heat or cold acts upon the centres controlling the diseased parts, thus altering the action from an abnormal to a healthy one. My object in this paper will be to show as clearly as possible, by means of a series of cases, the varied application of ice required in different subjects suffering from the same disease, and the impossibility of successfully treating the patients in any other than the way described. I will quote briefly from Dr. Chapman's works, and then proceed to apply the cases to the subject, first giving an account of them and their treatment; why the application acted curatively; and next, that the remedy used over any other spinal sections would have been unsuccessful, or even have produced disastrous results. In his work "On Cholera," page 186, he says "The application of the ice is greatly dependent upon the care and correctness with which it is applied!" On page 304, work "On Neuralgia," he speaks very emphatically, saying, "The solution of the problem—how to secure all the good, and to avoid all the evil which may arise from the use of heat and cold applied to the spine—is far more difficult than it may at first sight appear. It necessitates a thorough knowledge of each of the chief elements of the subject, experience in using that knowledge, circumspection, reflection, and the practice of a sort of strategic skill in the achievement of objects by indirect or circuitous paths, when attempts to accomplish the same purposes directly would probably be attended with failure, and even with danger. Gentlemen who, on a priori grounds, deny the possibility of producing untoward results by the application of the spinal ice-bag, will consult their own reputation and the welfare of their patients by refusing to permit themselves to be so far misled by their seeming scientific, but really prejudiced, skepticism, as recklessly to apply ice along the spine, confident that, at any rate, it can do no harm, even if it can do no good!"

These quotations do not express, by any means, all that Dr. Chapman uses to delineate the necessity for caution.

1 The indices are mine.
and understanding of the fundamental principles of his system, but are sufficient to make clear to any careful physician how much can only be obtained by careful study of the method, with a proper diagnosis applied thereto. I have treated three cases of eczema rubrum successfully by the use of the ice, applied differently in every case.

Case I.—In November, 1882, a Boston resident consulted me. He was a man of great height and large frame, twenty-seven years old, and was covered from head to foot with the eczematous eruption. Diagnosis appeared the most intense itching and burning over the whole surface, so that, as he expressed himself, "If it continued much longer he would become insane." The discharge from the buttocks and flexures of the thighs and scrotum, in all of which parts the dermis was much thickened, was so great that he required constant supplies of old linen beneath him in bed, to prevent a soaking of the mattress. The dermis of the palms of the hands and the soles of the feet were also much thickened, and very tender to the touch.

His history was that of a man who, for several previous years, had overworked both body and brain. Fifteen months before consulting me he had taken a very long and fatiguing journey from Boston to the mountains, and was attacked immediately afterward by eczema upon the buttocks. This attack proved transient and entirely disappeared. A few weeks after he was again afflicted, with an extension of the eruption over other parts of the body, and from that time until I was consulted he had never been entirely free from the disease. Any over-exertion, excitement, or suddenly catching a cold, or any rise in the temperature, travelling in trains, etc., produced a fresh eruption, with the consequent suffering. He had tried every method of treatment without permanent benefit, and was almost in despair of any help. He had no disease of any internal organ whatever, all the functions being performed normally. His brain was hyperemic, as shown by more or less sleeplessness, during three years previous to beginning the ice treatment. When I saw him he had been suffering for a week with a fresh outbreak over the whole body, including those parts which were chronically affected, and begged me, if I could, to stop the itching and burning. I filled a long Chapman bag sufficiently full to cover the whole dorsal and five lumbar regions, and applied it. I did not, however, apply to the cervical and upper dorsal region, for the head was hot and congested, and the ice placed over the sympathetic centres in this region would have further added to this abnormal condition, and perhaps have caused fatal coma after a few hours. The result, after twenty minutes of this application, was the most astonishing. "The itching and burning, which had been almost unbearable, ceased over the whole body!" and the patient became quite drowsy at the same time. He slept through the night, waking about every two hours to refill his ice-bag, as the itching and burning were renewed every time the ice melted. During the first five days and nights, ice was constantly used over the dorso-lumbar region, for no ill result followed its continuous application, but rather a return of the irritation of the skin immediately the cold was removed from the spine. By that time, however, fresh eczematous vesicles had ceased to appear, and I thought it better to see if the same result, viz., a gradual improvement, would not be sustained by a lessened use of the remedy. The patient had had much sleep, and his general nervousness was greatly calmed. On the sixth day, in the afternoon, I removed the ice for a couple of hours.

The patient's head became hot at once, with some throbbing of the temporal arteries, accompanied by stupidity of thought like that of a person suffering from a severe cold. I suspected a slight cerebral congestion. The symptoms were not sufficient to cause me great anxiety, yet I could not quite explain them, so was somewhat disquieted during the night that followed as to the successful result of the treatment. During the twenty-four hours succeeding, ice was used sixteen hours, and in the afternoon of the seventh day the patient remained in the same condition as above. It suddenly occurred to me that the brain having been sufficiently hyperemic when I began the treatment to prevent use of the ice over the cilio-spinal region, it had again become hyperemic from a cessation of the constant application over the dorso-lumbar region, thus allowing the arterioles in the brain to dilate; by withdrawing suddenly the dilating power over the arterioles of the lower body, through the action of the ice upon the sympathetic centres of this region. Acting upon the suggestion, I filled a lumbar bag of Dr. Chapman's half full of hot water, at a temperature of 120° F., placing it over the cilio-spinal region, and to my great satisfaction in an hour all hyperemia of the brain vanished, while the patient became quite rational, with a cool, moist skin. During this evening he fell into a refreshing sleep, which continued with waking intervals for twenty-four hours. From this time he steadily improved, gaining greatly in weight, with a large appetite, good nights' rest, a quiet nervous system, which he had not known for three years previous. The duration of the application of the cold ice from the lumbar region, and its sudden cessation, the hyperemia of the brain disappeared, it was applied in the full-length bag, from the fourth cervical to the last lumbar vertebrae, to control the disease upon the head and upper extremities. Much suffering was experienced from the third until the fifth week of treatment from occipital neuralgia, which gradually disappeared under the use of the full-length bag. The eruption disappeared, but recurred in a small round patches, and he was feeling better than he had for years.

Being a man in active business, and having many business troubles, during the next three months he had several relapses, which were, however, much more readily than at first by the same remedy, each relapse covering less of the body than before, until the last occupied only a small place upon the buttocks, not inconveniencing him greatly. This was in May, 1883, since which time he has been in California, working steadily, and has had no return of the trouble while there. On playing Easter again last year, the trouble disappeared, making a reappearance in a slight form. The ice is used every second day, and prevents further progress.

November 22.—The patient is now quite well. Taking into consideration the length of time that he had suffered before using spinal ice treatment, the amount of suffering he has undergone, the general physical prostration produced thereby—the fact that while under treatment great mental anxiety was endured, and that the patient, since the skin trouble was subdued, has, against my judgment, continued mental and physical labor to as great a degree as formerly, the result is a remarkable one, and I feel well assured that, unless some unusual mental or physical nervous shock is undergone, he will not be troubled in future.

In deciding to use ice in eczema, I argued upon the principle advocated by Dr. Chapman, that there are trophic nerves supplying each cell composing the dermis, regulating the amount of nutrition to that cell from the arterioles, and at the same time regulating selection from the blood of proper material to nourish the cell. When the centres controlling the skin-cells are unduly excited, that is, congested, according to Dr. Chapman's views, not only is the "selective affinity" of these cells abnormally increased in eczema, creating hypertrophy of the skin itself, but there is excreted from the arterioles so large a quantity of serum that the vesicular elevation of the epidermis takes place, for want of the characteristic eruption. Acting upon the hypothesis here expressed, I decided that cold over the congested centres would relieve them of their excess of blood, and prevent abnormal nervous
force to the skin-cell due to the activity of the centres, and would further act by giving rest to the long-congested vessels of the centres, allowing them to recover their contractility, so that mental or physical shocks would no longer produce these symptoms of neuro-sensibility. The cases reported speak favorably for the truth of this hypothesis, though treated by ice over different sections of the spine. Now in this case, the ice had been used at first over the cilio-spatial region, before the hyperaemia of the brain had been quite overcome, the result would have been such intense congestion of that organ as either to alarm the physician, to make him as to cause a cessation of the treatment, or even to produce a coma so severe as to result fatally. A physician who had glanced over Dr. Chapman's system without study, retaining only in remembrance that it meant “ice to the spine,” might very naturally have made this mistake, and either have pronounced it a failure or else have considered the treatment so dangerous as to be useless as a successful medical agent; damning the system, and not his own ignorance or carelessness.

Case II.—This was the first treated, in August, 1881. The condition of the patient when first seen was: General anemic appearance, with a pale face and lips, anxious expression, poor appetite, shortness of breath when walking, and frequent palpitation; she was sleepless but never wakes refreshed, bowels regular, some nasal catarrh. The case showed a deficiency of nourishment in the brain and whole upper extremity, arising from a contracted state of the terminal arterioles, and at the same time a sufficiently powerful congestion of trophic centres supplying the hands and wrists to excite an excessive flow of serum from the partially contracted blood-vessels, to produce the eczema; or it may be said, this excessive effusion of serum from blood-vessels, which although contracted generally in the brain and thoracic and brachial regions, yet, owing to the excitement of trophic nerves in the parts covered by the eczema, were in these parts kept dilated by this excitement. Ice, covering the cilio-spatial region of Chapman, was thus indicated, to dilate the arteriole circulation through the ependyma, thorax, and brachial regions, to supply thereby a more complete nourishment to the anemic parts, and at the same time act as a sedative to the congested trophic spinal centres, lessening the excitement of their terminal nerves in the dermis of the hands and wrists, to allow the nerves of nourishment to act more abnormally on the dermis and give rise, in the region of the trophic centres controlling the hands. The ice was used three hours per day, in a lumbar bag over the lower dorsal region. This dilated the blood-vessels in the pelvic body and lower extremities, thus driving the excess of blood from the head, thorax, and arms. Then a narrow bag, only wide enough to cover the spinal cord, and filled with ice, was placed over the cord in the cilio-spatial region, to relieve or restrain the excessive congestion of the trophic centres controlling the hands. The bag was used for four weeks, several hours per day, afterward for a shorter period. The patient's eczema began to improve at once, while the face became clear, with almost a fresher complexion. The conjunctiva were no longer injected, the hot flushes ceased, the appetite improved, and the distressing sensations caused by hot weather, in the head and thorax, were entirely relieved. In six weeks the patient had almost recovered, and left the city in July, 1881. Since that time she has remained quite well. This case illustrated fully how much thought is required in applying the treatment, and is as forcible an argument as can be used against a careless or ignorant application of the same. It was due to the application of the ice to the neuro-sensory tissue, that the skin at once became clear, and that the skin on the back, which was the first to become clear, was the last to return to a normal condition.

Case III.—A lady from New Orleans, who was recommended to come to me by Dr. Francis B. Greenough, July 14, 1883. She presented the following symptoms: Very severe neuralgia of the left lower jaw, which has now lasted three weeks. The pain is continuous, but worst at night, and she is unable to obtain sleep unless one-half a grain of morphia is administered each night. Has had “dumb chills” during the past year, suffers from frequent “hot flushes” in the head, which is very hot when the neuralgia is most severe. Hands and feet cold most of the time; often has cramps in and jankings of the legs at night. The face is covered with a dark red and scaly eruption. Eyes heavy, with a muddy looking sclerotic; suffer from general weakness,小姑娘 is bad and was so before using so much morphia; appetite poor, and has lost largely in weight. There was no organic disease that I could determine, and my diagnosis was general hyperaemia of upper body, anemia of the trunk and legs; or, in other words, there was excitement or congestion of the vasomotor and motor centres in the dorsal lumbar region. She felt better, was more animated in her neck, thus allowing the head to be constantly hyperemic. Dr. Chapman's system intimated as treatment the application of ice over the congested dorso-lumbar centres, to be used for several hours each day, as the case was chronic, in order, by dilating the blood-vessels in the lower extremity, to restore a normal circulation to those tissues, and at the same time relieve the hyperaemia of the head and brain, which was the cause of the pain and sleeplessness.
At noon of the 15th ice was applied over the dorso-lumbar region, for twelve hours between that time and noon of the 16th, with a resulting night’s rest without morphia, and only a few paroxysms of pain. These spasmodics were well removed the next day, the head being heated by heat to the cilio-spinal region, and the ice continued as before. This patient had a cavity in one of the molar’s, directly over the chief seat of the pain. It was filled at once, and she left the city for the night, requiring one-fourth grain of the morphia to produce sleep and entirely ease the pain. From this time forward her progress was one of surprising gain. The sleep became relatively deeper; by the end of four days the pain had entirely ceased; in two weeks the rash had become much lighter upon the face, the eyes bright, with a clear sclerotic, the head was no longer hot, jerks of the limbs at night ceased, the appetitae good, the bowels more regular in action, and a good deal of exercise could be taken without exhaustion. At the end of eight weeks, the use of the ice having been steadily lessened, she was pronounced almost well, and left the city on her way to the South. Treatment to be continued for several weeks, one and a half hour every other night. If the ice had been used in this case over the cilio-spinal region the result would have been to increase the pain, the congestion of the head, the sleeplessness, and perhaps the fatal crisis. The manner of cooling the end of the disease to any considerable extent would have been unsuccessful, and the system have appeared absurdi to both physician and patient.

The relief was effected by the action of the ice over the congested, and thus overacting or excited, dorso-lumbar vasomotor centres; driving from them the excess of blood, and subduing their excitement so that the brain vessels in the abdomen might be rendered more nourishing the weakened bowel muscles, and procuring a cessation of the constipation by a re-establishment of their peristaltic action; and by supplying the legs with their normal amount of blood, relieving the head and brain of their excess, which was the cause of the troubles in that organ. The feet became permanently warm. This lady gained eighteen pounds in weight during the eight weeks under my observation. There is no rule in Dr. Chapman’s system by which the length of time of ice application may be certified to in cases of the same disease in different persons. In an individual of strong muscular and nervous organization, without organic disease, the time of a few days might be necessary to overcome the troubles, before the treatment is beneficial, or rather curative, only by its application at first many hours per day, to prevent severe reaction in the intervals between the applications. It may be easily understood that ice applied in chronic cases, for short intervals at first, will only give rise upon its removal to a greater congestion of vasomotor centres, and a firmer contraction of the arteries under their control. In all cases the history of the life and family must be thoroughly investigated, while, as Dr. Chapman says, in those cases which seem, upon a first examination, unfit for neuro-dynamic treatment, a physician who has thoroughly studied and apprehended the method may, by a sort of strategic skill, assist the progress of the disease.

Is congestion of the trophic skin-centres the cause of eczema? From the results of the treatment, although the cases are few, it seems to me probable, and I shall continue such treatment in preference to local applications, both on account of the rapid relief given to the itching and burning felt by the patient, its permanently curative action, if continued sufficiently long, and because of the cleanliness of the method.

The ammoniaphone.—Dr. Carter Moffat has invented an apparatus called the ammoniaphone, for producing an artificial Italian atmosphere, that has a remarkable tonic effect upon the voice. The apparatus contains an absorption chamber impregnated with a peroxide of hydrogen, ammonia, and some other ingredients, and through this, air is drawn into the lungs.

TREATMENT OF WRY-NECK BY SULPHATE OF ATROPINA.1

By W. M. LESZYNFSKY, M.D.,
PHYSICIAN TO THE CLASS FOR NERVOUS DISEASES IN THE DEMILIT DISPENSARY; FOUNDER OF THE CLINIC FOR NERVOUS DISEASES IN THE NEW YORK POST-GRADEATE MEDICAL SCHOOL AND HOSPITAL, ETC.

On December 6, 1883, Mary K.—was presented at my clinic in the Demilt Dispensary, accompanied by an attendant, as she was unable to walk about without assistance. The following history was elicited from the patient and her friends: She was born in the United States, is twenty-one years of age, and unmarried. Her parents are healthy. Her uncle, it is said, had paralysis, but recovered. Family history otherwise good. She is of a "nervous" disposition and has always been subject to constipation and headache. Menstrual function regular. A few years ago she had rheumatic pains in her feet and occasional redness and swelling of great toes. Her occupation during the last two years has been that of a book-keeper in the Bible House. In performing the duties of her position she was obliged to keep her head turned to the left side while comparing the foldings with a gauge, which required almost continuous concentration of attention.

About three months ago, she first noticed that her head was inclined to turn to the left, when she was not engaged at her usual employment. Nothing was thought of this at the time. Two weeks subsequently spasmodic action of right side of neck and shoulder manifested itself. The spasms developed gradually, increasing in intensity, and has now reached a condition of such severity as to occasion great inconvenience and suffering. Her entrance to the room was effected in a very precipitate manner, as she stumbled and struck her head against the door. This awkwardness was due to the fact that her head was markedly rotated, with the chin resting upon the left shoulder, thereby interfering with the usual method of seeing where she was going, and producing involuntary nausea.

The right sterno-cleido-mastoid muscle was hypertrophied to about three times its normal dimensions, and was undergoing continual spasmodic action both clonic and tonic in character, the clonic convulsions being so frequent as to keep the muscle almost in a permanent state of tonic contraction. The head was forcibly jerked to the left at each convolution of about fifty times per minute, with an occasional intermission of a few moments, when the muscle would assume tonic spasm. With great difficulty I succeeded in forcibly drawing the head to the opposite (right) side, but when pressure was removed it would immediately spring back to its accustomed abnormal position. The clavicular portion of the right trapezius muscle was also affected with clonic spasm, causing the right shoulder to jerk simultaneously with the head. The convulsive movements continue at night, and are attended with so much pain in the neck, occi-
put, and shoulder that she has been unable to sleep during the last four days.

The left sterno-mastoid muscle can barely be outlined, and is apparently atrophied from disuse. I decided upon the following plan of treatment: One daily injection of a solution of sulphate of atropia (\(\text{m} \text{v.} = \text{gr.} \frac{1}{2}\)) into the substance of contracted muscle, commencing with one-eightieth of a grain, and increasing the dose daily until relaxation takes place; in conjunction with the daily application of galvanism to convulsed muscle, and fradization to left sterno-mastoid. To alleviate her suffering and produce sleep, she is to have chloride hydrate, gr. xv., with ext. conium fl., \(\text{m} \text{x.} \), at night before retiring; pil. rhei co. No. ii. to relieve constipation.

December 7th.—Slept well last night. Bowels acted freely this morning. Injected \(\text{m} \text{vii.} \) of atropia solution. Galvanism, faradization; chloral and conium at night. December 8th.—Slept well. Atrop., \(\text{m} \text{ix.} \). galvan-
The clonic character of spasm has markedly subsided, and the tonic contraction now seems to predominate. The left sterno-mastoid muscle is increasing in size and strength under the daily application of the faradic current.

When commanded to do so, she is able, without assistance, to rotate her head to the opposite (right) side, and retain it in the erect position for two or three minutes. She sleeps fairly well. Appetite good. Bowels regularly active. Atropia m. xii (nearly the 3/4 grain); galvanism, faradization; sod. brom., gr. xx. t.i.d.

December 27th.—Atrop. m. xii.; galvanism, faradization; sod. brom., gr. xx. t.i.d.

December 28th.—Atrop. m. xii.; galvanism, faradization. Troubled with flatulence. Sod. brom. increased to gr. xxv. t.i.d. combined with charcoal and peptic.

December 29th.—Very much improved. She is rapidly gaining control over muscle. Atrop. m. xii.; galvanism, faradization; sod. brom., gr. xxv. t.i.d.

December 30th.—Atropia injection reduced to 3 m. x.; galvanism, faradization; sod. brom., gr. xxv. t.i.d.

December 31st.—Still improving. Administration of atropia discontinued. Galvanism, faradization; sod. brom., gr. xxv. t.i.d.

January 1, 1884.—Galvanism, faradization; sod. brom., gr. xxv. t.i.d.

January 2d.—Nearly well. Galvanism, faradization. Use of bromide was continued. Ordered cod-liver oil with 1/2 gr. hypophosphites co., 3/16, and Fowler's solution, 5 m. t.i.d.

January 4th.—She is able to take care of herself and walk with head erect and can rotate it sufficiently to permit of chin pointing over right shoulder. Her entire demeanor and disposition have changed; all manifestations of mental depression have disappeared and she is evidently happy. Occasionally her head is inclined to the left. All evidence of clonic or tonic spasms has vanished.

It will be observed that the initial dose of atropia was one-eighth of a grain, which was daily increased in amount until on the twentieth day she was receiving nearly one-sixth grain (the maximum dose), which was continued in the same quantity daily for four days, when recovery supervened.

It will also be noticed that no decided improvement was shown until the injection of nearly the one-sixth grain had been administered. All other treatment was deemed auxiliary to the atropia and I consider that recovery was due to the persistence in its use.

In looking over the literature, particularly in reference to the use of atropia and the doses employed in the conditions of muscular spasm, I find the following cases:

1. In a clinical lecture, delivered at the Pennsylvania Hospital, nearly sixteen years ago, on "Certain Forms of Muscular Rheumatism, particularly Wry-Neck, and Its Treatment," by Prof. J. M. DaCosta, in directing the attention of the profession to the use of sulphate of atrophia, he says: 'The muscles affected were the sterno-cleido-mastoid of one side and the trapezius.

Frictions and the ordinary remedies were of no avail, and one-fiftieth of a grain of sulphate of atropia was directed to be injected just over or into the rigid parts, hoping thus to relax them. The hypodermic injection was administered on the 8th of March, and at once a decided amelioration was observed, the same quantity was made use of on the 9th, and on the 10th it was noted that the stiffness of the muscle was almost entirely gone. The remedy was repeated and on the 12th the neck was supple; all distortion had disappeared; the head could be moved in every direction freely and without pain.'

In a case of hysterical trismus of nine months' duration, in the practice of Dr. John C. Shaw, of Brooklyn, N. Y., recovery took place under treatment by hypo-
dermic injections of large doses of sulphate of atropia. "After injecting atropia for four days, during which time I gave one-fifth grain, the trismus, which had lasted nine months, ceased. The largest quantity I ever gave at one injection was one-sixth grain, and the largest quantity in one day one-fourth grain. Undoubtedly these are large doses; but I used this remedy as I would opium in peritonitis, with no regard to any arbitrary dosage laid down in books, but until I got the effect. It will be observed that I carried my doses up gradually, watching my patient closely." In this case active delirium had produced after one-twentieth grain and in had been administered. Dr. Shaw has lately informed me that this patient has ever since remained free from trismus, etc., has married and had one or two children.

3. In a patient with hysterical wry-neck, treated by Hammond, by atropia subcutaneously, he commenced with one-fifth grain and gradually increased it to over one-thirty-fifth grain. In reporting the case he writes: "I continued to increase the quantity gradually daily, till on the 10th 'there was a slight amelioration perceptible. She was then getting one-thirtieth of a grain. Amendment from this time was steady under more gradual augmentations of the doses, and on the 23rd day the distorsion was gone and the muscle was fully relaxed. Treatment was then altered to the patient and she continued well to this day, though still strongly hysterical.'"

4. Patient of D. H. Cullamore, F.R.C.S., etc. "A case of tetanus cured by hypodermic injection of sulphate of atropia, one-fortieth grain every four hours for six consecutive days. Its administration was not followed by any of the easily recognizable symptoms of the disease."

5. Case of Mr. James Adams, of London, "tetanus cured where one-third grain of sulphate of atropia had been injected in divided doses within twenty-four hours."

In all of the above cited cases (excepting Case 3) the patient was in a hospital and under constant observation. Had either of them been an out-door patient like my own, or one who could have been seen but once a day, it would not only have been impracticable, but extremely hazardous to use such enormous doses. It seems to me, that in office patients the safest plan is to carry the dose up gradually, at the same time carefully noting its effects. In the case of my patient, I did not permit her to have a half hour after administration of the drug. I will venture to state, in view of the favorable result obtained with such carefully graduated doses, extending over a period of twenty-four days, that, had the patient been in circumstances which would have insured close attention, she might have recovered in a shorter time under more rapid augmentation in the quantity of atropia administered.

It has not been an infrequent occurrence to hear of cases of opium poisoning treated by large doses of atropia subcutaneously, but in the present paper reference to these histories is intentionally avoided.

My object in presenting this contribution is not only for the purpose of recording a successful result from treatment in one of a class of cases upon which administration of the drug. I will venture to state, in view of the favorable result obtained with such carefully graduated doses, extending over a period of twenty-four days, that, had the patient been in circumstances which would have insured close attention, she might have recovered in a shorter time under more rapid augmentation in the quantity of atropia administered.

PARTIAL DISLOCATION OF THE OCCIPITO-ATLLOID ARTICULATION—REDUCTION—RECOVERY.

BY P. C. COLE, M.D.,
NEW YORK.

On the morning of June 21, 1883, I was called to see Miss L. M—, aged twenty-four years.

I found her sitting up in bed, with an anxious expression of countenance, suffering intense pain, her face turned toward the right shoulder and the chin depressed toward the chest.

I was informed that being in the habit of retiring late, it was customary to place her letters on the foot of the bed that she might read them before rising.

Half waking from a disturbing dream, turning her head suddenly to see if there was a letter from her sister, then absent in Europe, she felt something give way, heard a snap, and found she could not move her head. She had been lying on her stomach.

She summoned assistance, and her relatives, supposing it was "a crick in the neck" had exhausted the domestic remedies of rubbing, lotions, etc., before my arrival, which was one hour after the accident.

On attempting to restore the head to its normal position I found it immovable, and so did my assistants, although there was apparently no spasmodic action of the muscles to prevent it. I now counted the pulse, found it 44, and at once recognized the gravity of the case.

I should have been very glad to have had counsel, but fearing the possible results of delay, determined to assume the responsibility of attempting reduction without professional assistance.

On careful examination I thought I detected slight malposition of the vertebra. The patient still sitting up in bed, I clasped the head firmly with both hands, and without attempting to change its position, made slow and steady extension until the body was raised so that her heels only rested on the bed. Holding her thus suspended for a short time, I found, to my inexpressible relief, that I was able to return the head to its normal position without difficulty. Laying her carefully down, and retaining the head in position with pillows, I again counted the pulse, and found it had risen to 72. The intense pain had ceased while suspended, and she suffered only from a dull aching sensation, and the great danger she had incurred, and enjoined absolute rest.

During the afternoon her pulse commenced to fall, and by evening it was again 44. For the next three days the patient suffered but little pain, the pulse remaining steadily at 44; fifth day, 65; sixth day, 72. For the next few days moving her in the bed, although done with the utmost care and never any of my own, I would temporarily send the pulse down to 44.

July 4th.—In moving her the head was slightly jarred, causing intense pain, fall of pulse, and alarming symptoms of syncope. Brandy was given, and in the course of an hour she had recovered from all unpleasant symptoms.

Dull pain had been felt from the time of the accident, and a slight extension now had the relief. I had an instrument made to rest on the shoulders, back, and chest, supporting and making slight extension to the head by means of a steel spring, which admitted of a nodding but not of a lateral motion. This gave great relief and was worn day and night.

After the second week Miss M— was able to sit up, from this time on her improvement was steady. She went to the seaside, and on her return, some two months after the accident, was able to dispense with the use of the instrument. She still felt a little pain if she made a sudden movement, and was obliged to be careful.

During her illness the temperature varied but slightly from normal. No medicine except mild saline cathartics were used.

At the present time, nearly seven months after the accident, she is in perfect health.
I am well aware of the difficulty of diagnosis in injuries affecting this region. Subluxation of the occipito-atlial might be mistaken for that of the atlo-axoid, a much more common accident. In this case, however, I feel sure of my diagnosis. The pain and tenderness, which persisted for weeks, were principally confined to the left side, about the interspace between the sterno-cleido-mastoid and trapezius. No pain was experienced in the front part of the neck, as would have been the case if the odontoid ligament had been ruptured. Lateral motion of the head caused pain long after the nodding motion ceased to cause any inconvenience.

The literature of the subject is very scant. Gross, in his "System of Surgery," refers to it in these words: "A few cases of traumatic luxation of the occipito-atlal articulation have been reported; but, so far as I know, all, except one, and that was only a partial displacement, promptly proved fatal. The accident, until recently, was regarded by most writers as impossible, on account of the firm connections and restricted motions between the two bones."

Bellevue Hospital, New York.

Reported by Fraser C. Fuller, M.D., Late House Surgeon, Bellevue Hospital.

Fracture of Pelvis—Laceration of Urethra—Perineal Section—Recovery.

Bernard D.——aged forty-one, boat-builder, entered Ward 10, Bellevue Hospital, August 18, 1883, during the visiting service of Dr. Charles McBurney. About eight hours before, while assisting to hoist a boat into the loft of a building, the hoisting apparatus gave way and the boat fell upon him, crushing him to the ground, the greater part of the force being exerted upon his pelvis laterally, i.e., through the acetabula. He had endeavored to walk, but found it impossible, was carried to his home and later transferred to the Hospital. At the time of entrance he was very weak, pale in countenance, and very thirsty, and to relieve his thirst he had been drinking freely of ice-water and beer. Examination about the pelvis showed a bloody discharge from the urethra, ecchymosis of the perineum, which was increasing in extent, and great tenderness in the rami of the pubes and ischia, particularly of the left side. An attempt had been made before he entered the hospital to catheterize the bladder, but with negative results. Similar endeavors in the ward were also unsuccessful, the instrument suddenly jumping from the urethra laterally into extra-urethral tissue.

Dr. McBurney being away from the city, a consultation of the house staff was held, and it was decided that perineal section was necessary. The man was so weak that I almost feared to operate, but decided to risk the operation at that time in order to prevent extravasation of urine. Up to that time I think that no extravasation had occurred, although the bladder was very full. A staff was passed into the urethra and its point carried down to the seat of laceration and held in the median line. This served as a guide in the operation. A moderately large incision was made and the urethra soon reached. The laceration was in the membranous urethra, especially its anterior portion. At this time a large amount of extravasated blood escaped from the wound, but no urine. With some little difficulty the proximal end of the lacerated urethra was found and a silver forceps was passed into the bladder, from which flowed a large amount of clear urine. The forceps passed into the wound and carried to the right was able to plainly feel the fractured bone, the rami of the pubes and ischium of the left side, and distinguish the overlapping and deformity that existed. The separation between the ends of the lacerated urethra was nearly an inch, it being torn completely across.

The silver catheter was tied into the bladder, the wound loosely packed with iodoform gauze, and the patient put to bed. He appeared stronger after the operation than before it, and gradually rallied to a fair condition. The fracture of the bones was not treated, no attempt being made to immobilize or fix the pelvis.

On the third day the silver catheter was removed and replaced by a soft one. The perineum and scrotum were now inky black from the old extravasation.

On the 26th, eight days after the operation, the wound began to suppurate, and the patient developed a slight cystitis. He was placed on a water-bed, which was a great relief to him. The catheter was removed from the bladder, and his bladder catheterized and washed out at regular intervals; suitable internal medication being employed, especially boric acid.

September 15th.—An attempt was made to pass a sound through the entire urethra into the bladder. No effort had been made previous to this time, as it was not deemed advisable, considering the patient's condition. The attempt being made it was found impossible to enter the bladder with the instrument. I sound found the urethra at the seat of the laceration. He continued to urinate by both the urethra and the fistula until October 10th, when I did an external urethrotomy and passed a No. 18 (English) sound into the bladder, the patient being under ether. Subsequent attempts at passing sounds without ether were attended with difficulty, the pubic arch seeming to lower down still more than usual, producing a very sharp angle at the triangular ligament. This difficulty increased until October 27th, when Dr. McBurney performed an internal urethrotomy, also dividing a bridge of tissue in the membranous urethra through the perineal fistula. The patient has since made an uninterrupted recovery, and now takes a No. 19 English steel sound without difficulty, and his perineal wound is entirely closed. He is a well man, walking perfectly, his only failing being a slight stoop, which can be traced to his pelvis.

New York, January 5, 1884.

Time Required for Stomach Digestion.—E. Jessen has made some experiments on the time required for the digestion in the stomach of several articles of diet. The stomachs of the persons submitting to the experiment were emptied by the aid of a pump, and one hundred grammes of raw or cooked meat mixed with three hundred cubic centimeters of water and of other were introduced. The experiment was considered ended when the stomach-pump could remove no particles which exhibited the microscopic appearances of muscular fibres. The results were as follows:

<table>
<thead>
<tr>
<th>Food</th>
<th>Time Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw and finely-cut beef</td>
<td>2 hours</td>
</tr>
<tr>
<td>Partially-boiled beef</td>
<td>2½ hours</td>
</tr>
<tr>
<td>Well-boiled beef</td>
<td>3 hours</td>
</tr>
<tr>
<td>Rare roast</td>
<td>3 hours</td>
</tr>
<tr>
<td>Well-roasted beef</td>
<td>4 hours</td>
</tr>
<tr>
<td>Raw mutton</td>
<td>5 hours</td>
</tr>
<tr>
<td>Raw veal</td>
<td>2½ hours</td>
</tr>
<tr>
<td>Raw pork</td>
<td>3 hours</td>
</tr>
</tbody>
</table>

The digestion of milk was examined in the same manner, a quantity of milk being used of which the percentage of nitrogen was equivalent to that of one hundred grammes of beef.

605 cubic centimetres raw cow's milk .... 3 hours
600 cubic centimetres semi-boiled milk .... 3 hours
602 cubic centimetres sour milk .... 4 hours
675 cubic centimetres skimmed cow's milk .... 3 hours
656 cubic centimetres raw goat's milk .... 3½ hours
Progress of Medical Science.

LYMPHOMAHA FROM THE NOSE IN LEUCOCYTHEMA.-Dr. Cornil relates the case of a patient suffering from leucocytemia who had a discharge from the nose of a thick, transparent, grayish fluid. It flowed slowly but constantly, and was neither thin like the discharge of a commencing corzva, nor opaque like that of a more advanced nasal catarrh, but contained a large quantity of white corpuscles. The patient did not sneeze, nor were there any turbidities in the fluid. The surgeon found the mucous membrane of the nasal fossa was seen to be smooth, without ulceration, but thickened in places. The thickened parts presented a gray color on section. They were formed by an infiltration of the connective tissue with a mucous transparent fluid, like lymph. It was this leukemiac infiltration of the Schneiderian mucous membrane which was the cause of the nasal lymphoma.

-Revue Medicale, August 11, 1883.

ACUTE NECROSIS OF THE RIBS.-At a meeting of the Liverpool Medical Institution, Dr. J. Cameron showed a preparation of the ribs, and a post-mortem photograph by Mr. Paul, of the following unusual case. A Mexican sailor, aged nineteen, was admitted into the Southern Hospital in a condition of exhaustion, with pleurisy and pneumonia at the right base. He had a temperature of 104°F, dyspnea, and cough; he slept badly, and was very restless. The liver and spleen were enlarged, and the muscles; what tender. The gums were spongy, and mastication was painful; there were also pains in the legs, with some swelling about the knees, and a small sore over the left great toe. This sore was produced by his shoe, and had been the commencement of his illness two and a half months ago; he having been laid up on board his ship during this time with symptoms of low fever. A day or two after admission it was noticed that his ribs were in a peculiar movable condition; and since he did not refer any pain to the part, it was believed to be of old standing. In the hospital his febrile symptoms increased; he became delirious and semiconscious. The dyspnœa and restlessness increased, and in ten days he died. At the post-mortem examination, on reflecting the skin, the sternum with the costal cartilages at once fell back into the chest, the latter being all separated, from their attachments with the ribs, except just at the upper part. The ribs, on the contrary, projected from the neighboring soft parts for three or four inches, the third to the sixth, on the right side, and the fifth to the eleventh on the right. Before removing the skin, each of these ribs had been surrounded by an abscess. No evidence of pyemia was met with; but pleuroneumonia at the right base, and enlargement and congestion of the liver and spleen, were found. Dr. Cameron concluded that the patient had suffered from malarial fever, and that the peristalsis and necrosis of the ribs were a sequela of this. He quoted Sir James Paget ("Of the Occurrence of Necrosis, especially of the Ribs, after Typhoid, Roman, Neapolitan, or other Malarious Fevers") in support of his opinion.—British Medical Journal, December 15, 1883.

SALICYLIC ACID IN ECZEMA.—Lassar (Monatshefte für praktische Dermatologie) points out that salicylic acid is specially useful in eczema, and particularly when used as a two per cent. vaseline salve or vaseline zinc paste. In the common eczemas of the head in children, so numerous in Buenos Aires, after three thorough cleansings, the daily application of the following salve nearly always suffices to obtain rapid and lasting results:—B. Acid. salicilic., gr. x; Tinct. benz., m xx.; Vaseline, $j.; M. Pt. ung. On other parts, where a soft salve which easily melts as this is not suitable, where a firm dressing or drying effect is desired, the following paste should be rubbed on:—B. Acid. salicilic., gr. xx. Vaseline, $j.; zinc oxide; anyh. m. $j.; M. Leiniter tered., fiat pasta. So long as the secretion is abundant, the dressing should be daily renewed. Sometimes, when it dries hard, it tickles the skin; it should then be rendered soft by subsequent inunction with vaseline.

MULTIPLE DEGENERATIVE NEURITIS.—Dr. Strimpell relates the following case (Centralbl. für die Med. Wiss., October 27, 1883). A drunkard who had for several years experienced pains in his arms and legs, had, within the last year, suffered also from weakness of the lower limbs, which had recently amounted almost to paralyasis, extending also to his arms. He became confused both as to time and place. The sensibility of the arms was unaltered; in the lower limbs sensation was nearly obliterated. The reflex cutaneous phenomenon of the legs was feeble; tendon reflex was absent. The bladder and rectum retained their power. The optic disc was atrophied on both sides. Paralysis of the respiratory muscles and death occurred suddenly, three and a half months after the case came under notice. The posterior horns of the spinal cord, and the anterior roots of the nerves of the extremities, showed no macroscopic change, but the microscope showed atrophy of the nerve fibres, with fatty degeneration of the muscles.

DIABETES INSIPIDUS FROM SYPHILIS.—Dr. Sidney Phillips, at a recent meeting of the Harveian Society of London, read the notes of a case of diabetes insipidus, due to syphilis. The patient, a man aged thirty-three, had, ten years previously, been treated for a chancre, followed by secondary symptoms; and had since, at various times, suffered from the effects of syphilis. When first seen by Dr. Phillips, he stated that he was passing very large quantities of urine, as much as 15 pints in a night; he complained also of severe pain, increased at night, in the right fronto-parietal region, with localized tenderness; the right pupil was irregular from old ictic adhesions, and he had a gummy, of the size of a marble, in the substance of the tongue. He was treated by iodide of potassium, in large and increasing doses, and in three weeks he had made rapid progress toward recovery. The headache had ceased; he was passing a little over three pints of urine in the twenty-four hours, and the gummy of the tongue had much diminished in size. Dr. Phillips remarked that, in this case, the increased flow of urine was due to syphilis; but whether it was due to the lesion on the cortex of the brain was not so clear. In all the reported cases, where the lesion had been found as the cause of the polyuria, it had been situated at the base of the brain. Trouseau, however, recorded a case of polyuria, following an attack of ordinary hemiplegia, where the lesion was presumably elsewhere than at the base; and possibly, in the present case, it was due to the node on the surface of the brain, which softened and diminished in size under the influence of the iodide, as the gummy of the tongue was simultaneously observed to do.—British Medical Journal, December 15, 1883.

CARDIAC PALPITATIONS.—M. Peter explains the occurrence of palpitation of the heart as being due to different circumstances affecting its mechanical action (Arch. Med. de Paris). Palpitation may be due either to excess or defect of innervation. Under the first head come those forms of palpitation that result from stimulation of the ganglionic cells of the myocardium, from stimulation of the great sympathetic, or from increased activity of the heart in endeavoring to overcome an obstacle (spasmodic palpitation). The second form of palpitations results from a diminution in the activity of the pneumogastrics, from fatigue, or from an alteration in the myocardium (paralytic palpitations). Side by side with this kind of physiological anthesis, in palpitations being due either to excess or to defect in innervation, a form of pathological anthesis is also observed in the occurrence of palpitations resulting from plethora as well as from anemia.
THE MEDICAL RECORD.

THE MEDICINAL PROPERTIES OF ARLENTIN.—Arlentin, the alkaloid of uva ursi, is a potent diuretic, and becomes converted into hydrochinon and sugar by boiling with acids, or under the influence of fermentation. Dr. Menche reports (Arch. f. Pharm. 27, 1853), giving the following as the results of his observations upon the action of this alkaloid: 1. In many cases it has proved to be a valuable diuretic. 2. It may be given in large doses without detriment. 3. It becomes converted into hydrochinon in the human urine. Its action as a diuretic was noted in two cases; in one, a case of fever, the patient's urines were entirely over-seeded, and if it have the power of preventing the exudation of lymph from the blood-vessels into the lymph-spaces, it will enormously increase our power to prevent or to lessen dropsey. Dr. Gaskell has shown that dilute acids cause relaxation of the muscular substance of the heart and blood-vessels, while dilute alkaloids cause contraction. Under the influence of arlen- tons urine, the quantity of urine was augmented by about four ounces in twenty-four hours. In another case (tubercular peritonitis) the quantity of urine was augmented by about six ounces daily. In another instance the amount of the excretion was doubled under the influence of arlen tin. This medicine has, however, Dr. Menche reports, a specially beneficial action in vesical catarrh; and he suggests its employment in the place of uva ursi. In gonorrhoea, the author considers that it may supersede the use of injections by its conversion in the urine into hydrochinon.

HYDROTHERAPEUTIC TREATMENT OF DISEASES IN CHILDREN.—Professor Heubner has communicated to the Aeris. Vereinsb. für Deutschland a paper on the hydrotropic treatment of acute diseases in children. The children's alimentation is to give a portion of the whole body, that the cooling of it produces a marked effect on the whole organism. A cloth wrung out of water of the temperature of 60.8° F., should be placed over the chest, abdomen, and thighs of the child, and be well pressed down to the sides, the whole being covered with flannel. This should be renewed every half-hour with a temperature of 104° F., every hour when it is a little lower, and the treatment should be kept up for the greater part of a day. The temperature will be still more reduced by cold packing all over the body, but the younger the child, the less can cold be borne. Another use of hydrotherapy is to induce heat and perspiration, and this is useful in catarrhal affections. The wet bandages must be surrounded by a looser flannel covering, and may remain for an hour and a half without being moved. The addition of a little mustard to the water will assist the action desired.

THE PATHOLOGY OF DROPSY.—Dr. Lauder Brunton, in the Practitioner, September, 1883, contributes an able article on the pathology of dropsy. Dropsy is an accumulation of fluid in the lymph-spaces. In the normal condition these lymph-spaces are only moistened with lymph, whereas in dropsy they may contain it in great quantities. Dr. Brunton compares the lymph-spaces to a cistern; the arteries and capillaries are supply-pipes, the veins and lymphatic vessels are the exit-pipes. In health the lymph-spaces are merely moistened with lymph, because the veins and lymphatics at once carry it away from the spaces. If the lymphatics be ligatured, it is found that the veins are large enough to carry off the lymph, and the accumulation of fluid occurs. The lymphatics alone may also be sufficient to stop the flow of fluid when the veins are obstructed. Ligature of the veins produces increased flow of lymph through the lymphatics. The fascia between the muscles is spoken of as a pum ping arrangement, by which the lymph is drawn out of the muscle, and is passed onwards into the lymphatics. In suppuration, and in the experiments of Claude Ber- nard on the submaxillary gland, attention is drawn to the remarkable change which is noticed if a dose of atropine be administered to the animal under observation. If the choidea tympani be irritated after poisoning by atropine, the vessels dilate, the veins become full, but not a drop of saliva is secreted by the cells. This is usually called the atrophine stage, the terminal parts of the secretory nerves in the cells of the gland, but Dr. Brunton explains the phenomenon by assumeing that the atropine has so altered the vessels as to prevent the exudation of lymph from them into the lymph-spaces, at the same time that it has allowed the efferent vesseis to dilate; and thus atropine may have an action on the veins in which the action of acids, therefore, tissues will become odematous, whilst under the influence of alkalies there appears to be an arrest of the flow of lymph from the blood-vessels into the lymph-spaces. The increased permeability of the vessels may be produced by acids circulating in the blood, by acids applied to them from without, or by acids, or poisons which act like acids, absorbed from the intestinal canal or formed in the tissues themselves.

ALBUMINURIA IN CHILDREN.—M. Leroux, as the result of researches on the urine of 188 girls and 212 boys in the Hospice des Enfants Affaisés, has found that, in the case of children effected with marked albuminuria, the qualitative alteration appeared pretty constant, and independent of the time of examination; while in the case of children treated with antimony, he has found that it was in the afternoon between one and three o'clock, that is to say after a full meal, that reagents most often threw down a cloud more or less marked, whilst equally fresh urine in the morning only gave negative results. From these facts he inclines to the opinion of Johnson against that of Fürbringer, and accords a certain importance, as a factor in determining the presence of albumen, to the repast which has preceded the examination by two or three hours.

VALERIANATE OF ZINC IN DIABETES INSIPIDUS.—Dr. Cole, in the Lancet, records the notes of a case of diabetes insipidus in a lady, aged thirty, single, of delicate constitution, who had been ailing for nearly two years. The author commenced treatment with ergot, in gradually increasing doses of the liquid extract, until half an ounce every four hours was reached. This amount was maintained for more than a week, without the least effect on the disorder. Next valerianate of zinc was given in doses of five grains every six hours, and after a fortnight the patient was completely cured.

THE ACTION OF IODOFORM IN DIABETES MELLITUS.—Professor Boszolo (Archiv. Ital. de Biologie), after satisfying himself of the beneficial effects of iodoform in several cases of diabetes mellitus, caused a series of laboratory investigations to be conducted by his laboratory student, M. Balp, to determine the influence of iodoform upon the number of red corpuscles, the quantity of haemoglobin, and the arterial tension. These observations were conducted with great care, and by the use of the most approved physiological apparatus. In two cases of diabetes he found that iodoform in large doses—that is, to two grammes—did not remove the albumin and the quantity of urine, that it diminished the number of red corpuscles and of haemoglobin, and that it diminished the arterial tension. To explain the diminution of red corpuscles he cites the theory of Binz, that the iodoform, through the iodine which disengages itself, as in iodate of sodium, destroys the red corpuscles, and produces a condition of general anemia. In his cases the diminution must be progressive, and patients using iodoform would become rapidly anemic, which anemia has not been observed so far in cases under this treatment. The diminution of arterial tension would explain the effect of the drug in reducing the quantity of urine, in eliminating glucose, and on the quantity of corpuscles of hemoglobin; and the anemia would explain the view that the iodoform exerts influence on the centres, and especially upon the va-o-motor centres.
PERMITTING A TESTATOR TO PROVE HIS SANITY.

A bill has just been presented to the Legislature of this State allowing a person to file his will in the Surrogate's office of the County in which he resides, and permitting him to prove before his death his capacity for making a will. This bill is founded on the Michigan law, permitting such a course at the option of the testator, and which has been found to work well in that State. The great danger that estates will be put to large expense in sustaining wills against unscrupulous contestants, and the probability that unpleasant family secrets may be disclosed, has led many persons to devise some plan by which these evils might be avoided. It will be impossible, however, to frame any law which will entirely prevent litigation; the most that can be secured is a law which will enable a testator during his lifetime to establish both his capacity for making a will and the legality of its provisions. It is uncertain, of course, what advantage would be taken of such a law if it should be passed by the Legislature, but it is a plan which has merits, and persons ought to be at liberty to try it if they desire. The provisions of the act will be found interesting, and are as follows:

SECTION 1. To any will hereafter executed, the testator may make and annex his petition, to be sworn to before, and presented to, the Surrogate for the County where the testator resides, or to any court or officer having jurisdiction to take probate of wills, asking that such will be admitted and established as his last will and testament.

SEC. 2. Every such petition shall contain averments that such will was duly executed by the petitioner, without fear, fraud, importunity, or undue influence, and with a full knowledge of its contents, and that the testator is of sound mind and memory and full testamentary capacity, and shall state the names and address of every person who at the time of making and filing the same would be interested in the estate of the maker of such will as heir, if such maker should at the making of such petition become deceased, and may also contain the names and addresses of any other persons whom such testator may desire to make parties to such proceedings.

SEC. 3. Such court shall thereupon, upon request of such testator, appoint a time for the hearing of such petition, and issue citations to the parties named in such petition, and direct published notice of such hearing and have such hearing, after proof of service of citations and of publication of notice, in the manner as near as practicable, as is required for the probate of wills.

SEC. 4. If any person named in such petition shall be a minor, or otherwise under disability, a guardian ad litem shall be appointed by such judge to represent such person. On such hearing such court shall examine into the matters alleged in such petition, and into the testamentary capacity of such testator, and examine witnesses in relation thereto; and if it shall appear that the allegations of such petition are true, and that such testator was of sound mind and memory and full testamentary capacity, such judge shall make decree thereon, and shall cause a copy of such decree to be attached to said will, certified under the seal of said court, decreeing that the testator at the making of such will and such petition was possessed of sound mind and memory and full testamentary
capacity, and that said will was executed without fear, fraud, importunity, or undue influence; which decree shall have the same effect as if made by said court after the death of testator on the probate of such will; and such will having been so established, shall not be set aside or impeached on the ground of insanity or want of testamentary capacity on the part of the testator, or that the same was executed through fear, fraud, importunity, or undue influence.

FREE MEDICAL COLLEGES.

A bill has been introduced into the Legislature of Virginia appropriating an annuity of $7,500 to the Richmond Medical College. In return for this each member of the Legislature is entitled to appoint from his district a student who shall be allowed tuition at the said college free of all charge, except the sum of five dollars as a matriculation fee.

The results of such legislation, as well as the principles upon which it is based, are unquestionably bad, and we trust that the bill will not become a law. We shall gladly encourage the endowment, from any source, of medical colleges, provided such endowments are devoted to increasing the facilities for instruction and scientific work. But endowments which aim simply to gather in pauper students are opposed to public policy and professional interests. The State, indeed, has no more right to spend its money in teaching medicine than in teaching law, agriculture, or the arts.

We are surprised that a college which has so indignantly repelled certain criticisms which we have made as to the superiority of its methods, should thus stoop to begging of the Legislature for one hundred and forty free scholarships.

KOC'H'S LATEST INVESTIGATIONS IN CHOLERA.

We referred in our last issue to the fact that Koch had made another report upon the progress of his work at Calcutta. This report is a short one, and is mainly confirmatory of what the commission discovered while in Egypt.

Since their arrival in Calcutta, post-mortem examinations of eight cases of cholera have been made. In all of these, the peculiar bacillus before seen was discovered, both in the intestinal wall and in the dejecte. These bacilli have been cultivated and found to have a peculiar appearance and life history, which distinguishes them from other micro-organisms. Attempts to cause the disease by inoculating the bacilli in other animals have, however, as yet failed.

The intestines of various animals and of eight persons, dying from other diseases than cholera, have also been examined, and the peculiar bacilli not found.

Koch believes, therefore, that he has found the germ of cholera, although the fact is not yet demonstrated. Dr. Koch pays his respects briefly to the French commission and its alleged discovery of peculiar micro-organisms in the blood. These, he says, are only what can be discovered in other diseases. Besides, they have been seen and described by Dr. Cunningham as long ago as 1872.

CREDIT TO AMERICAN INVESTIGATORS.

It does not speak well for American medical men that the only addition which has been made to this country to bacterial pathology has been made, not by a doctor of medicine, but by veterinary surgeons.

If we cannot claim credit for our profession, however, we can at least insist that proper acknowledgments be paid our country by foreign investigators.

Dr. D. E. Salmon, in Science, calls attention to certain errors or omissions made by Pasteur in regard to the discovery of the pathogenic germ of hog-cholera (rouget-infected pneu-mo-enteritis). From this it appears that Dr. Klein, in 1876, first discovered the organism, but failed to recognize its function. In 1878, and in subsequent years, Dr. Detmers announced the existence of micro-organisms in this disease, but failed to prove that they were the cause of the same. In 1880, M. Mégnin described and figured the organisms of hog-cholera, and in the same year Dr. D. E. Salmon proved for the first time that these organisms existed in the blood of the living animal. He subsequently cultivated them, and showed that they were pathogenic. It was not until March, 1882, that M. Thuillier, the victim of the Egyptian cholera, independently made the same discovery. Pasteur gives the credit of it and priority to Dr. Detmers. Dr. Salmon writes: "Neither Pasteur nor Thuillier, nor any other investigators that I am aware of, have added one particle of evidence, except by way of confirmation, to that previously advanced by me. M. Pasteur is usually very particular in giving credit, but he does not seem to be keeping up with the progress of American science."

THE DANGER OF HYPODERMIC INJECTIONS OF CHLOROFORM.

At the meeting of the Académie de Médecine on February 12th, M. Bouchard made a contribution of much practical interest. For some years he had observed that hypodermic injections of one cubic centimetre of chloroform in rabbits invariably produced death within about twenty-four hours. Much smaller injections, if repeated daily, also produced death eventually. He found that the same phenomenon occurred in dogs, though relatively larger doses were required. The same amount of chloroform inhaled or injected directly into the veins did not cause death.

Hence it was inferred that there is something particularly injurious in the hypodermic method of administering this drug.

All attempts, however, to discover how the chloroform produced these fatal results were without success. Albuminuria existed, but the histological examination of the kidneys showed only an intense congestion, and the blood did not contain any extraordinary accumulation of urea. M. Bouchard could not attribute death to uremia. It appears to us that he lays too little stress upon the kidney lesion. His argument, however, is that animals to which chloroform is given by inhalation develop albuminuria also, but do not die.

Death could not result from any reflex cause, because after section of the nerves of the legs and injection of the chloroform the animals died. Neither could it be
due to any direct toxic effect, since intravenous injections did not prove fatal.

If we are to accept Bouchard’s statements, therefore, there is something mysteriously fatal in the hypodermic method, so far as regards chloroform and certain lower animals.

The query arises whether this danger applies to man. It is not a very imminent one, but it is worth bearing in mind. The hypodermic administration in one day of an ounce of chloroform might be fatal. The continuous daily administration of one-fourth or even one-tenth of this dose might also prove fatal.

In harmony with Bouchard’s conclusions are the similar experiments made by Colin of Alfort, with chloral.

DISTILLED WATER AND OLD AGE.

The Psalmist David allowed seventy years as the natural duration of life, Pythagoras placed the limit at eighty, London’s hygienic philosopher, Dr. Richardson, gives us ten more, while Flourens believed that man ought to live one hundred years.

There is no doubt that the physiological limit of human life has been slightly increased in the present century, and a hundred years later it may be found that old age comes on still more slowly and gently. For, with the increased uncertainty as to a future life, human energies are directing themselves with greater earnestness toward solving the problems of a more healthful and longer terrestrial existence.

The physiological chemist tells us that after the age of forty or forty-five, dis assimilation gradually begins to exceed assimilation, and the structures of the body slowly waste. Muscle and nerve, which are the “master tissues,” feel this first. The dynamic coefficient of both striped and unstriped muscle decreases after forty; the limbs become less supple, and the hollow viscera have a feebleer expulsive force. The nervous system is less sensitive and plastic. Impulses travel between centre and periphery with more difficulty. The individual loses spontaneity and becomes more automatic, more a creature of determined habits.

The lower tissues also undergo very marked and characteristic changes. The fibrin-factors of the blood increase in amount, the bones become drier, the cartilages ossify, and the arteries especially become the seat of fatty degeneration and calcareous deposits.

Dr. Richardson announces that “his experiments show” that the colloidal matter (protoplasms?) of the body in old age contains less water, and that its particles are consequently more cohesive. It is true, at any rate, that the total amount of water in the body is less.

The essential fact as regards senile changes is that the metabolic function is weakened. Consequently the food, instead of being built up into good tissue, is oxidized into less complex substances. The protoplasm turns out fat instead of new protoplasm, the circulatory apparatus becomes weaker, the blood stagnates, carbonic acid precipitates and earthy salts which it kept in solution are deposited.

Now certain recent philosophers have thought that, by preventing these fatty and calcareous changes, old age could be delayed. A Swiss physician, a few years ago, argued that lemons, i.e., citric acid, would accomplish this end, and saw immortality in lemonade. More recently, a writer in Knowledge, Mr. W. O. Dawson, has presented a new regimen sanitatis which he claims is the most rational and certain means of retarding old age. It consists in avoiding all food rich in earthy salts, and in taking, daily, two or three tumblerfuls of distilled water with ten or fifteen drops of dilute phosphoric acid in each glassful. The food freest of earthy salts is: fruits, fish, and poultry, young mutton and veal.

We can testify with Mr. Dawson that this kind of diet is harmless, but we are profoundly skeptical as to its efficiency.

Old age is part of the life history of the organism. There is that in the child at birth which determines very nearly when old age shall appear. Sensility is a failure of nutrition. We can only delay its appearance by living a life which puts no undue strain on the organism, and by furnishing it with the easiest means of working. We cannot expect to accomplish this end simply by cutting off certain deleterious supplies. If one would live long, let him especially take care of his “master tissues,” the muscle and nerve, when young. This means rational exercise of body and a well-balanced cultivation of mind. Brain workers live long. Brain and muscle workers longer still. No one has yet given better advice for the retarding of old age than did Christopher Hufeland, a century ago. Let those who wish old age study him and put no trust in distilled water.

THE PERIODICITY OF FEVERS.

Obermeyer’s discovery of the actions of spirilli in relapsing fever threw great light upon this point, which has not been developed in kindred diseases with the ingenuity that generally characterizes the medical profession. Le- fort, Weigt, Buchwald, and Guttmann, the latter in two hundred and eighty cases, have all corroborated Obermeyer’s observations, viz., that spirilli are always to be found during the paroxysm of the fever and its relapses; the numbers of these micro-organisms are proportionate to the severity of the attack; and they disappear entirely during the apyrexia, when not a trace of them is to be found. They died during the apyrexia, and only their eggs or germs remained, to be vivified in about fourteen days, and occasion another attack or relapse.

Relapsing fever is defined as an acute contagious fever, consisting of a febrile paroxysm of abrupt onset, with epigastric tenderness, vomiting, often jaundice, with enlargement of the liver and spleen, and terminating suddenly about the fifth or seventh day with free perspiration. Then follows an interval of complete apyrexia, succeeded by an abrupt relapse on or about the fourteenth day from the beginning of the disease, which runs a course similar to that of the initial paroxysm, but terminates on or about the third day. Convalescence usually follows upon the conclusion of this first relapse; but a second, third, or even fourth has been observed. Like intermittent fever, fatal terminations are infrequent, and enlargements of the liver and spleen are not uncommon.

These facts may justly incline some of our readers to believe in the bacillus maliariae of Klebs and Tommassi Crudeli, and to imagine that it has a somewhat similar,
but of course different, life-history from that of the spi-
rilla of Obermeier. The suddenness of the attacks, the
shortness of the paroxysms, the terminations in perspec-
tion, the frequency of relapses, and the congestions of
internal organs, especially of the liver and spleen, pre-
sent great similarities in the two diseases. But spiri-
rilla and bacille are very different, although very small things.
Quinine will destroy the latter—which are, perhaps, a
special variety of the bacteria of common vegetable de-
composition—but is comparatively impotent against the
bacteria of animal or septic decomposition, or putre-
faction. Although quinine fails to cure relapsing fever
and kill spirilli, yet a combination of quinine and camphor
was found useful during the intermission, and in the
early convalescence. But Riess, of Berlin, found a ger-
micide, viz., salicylate of soda, very effective in reducing
the temperature, and when given in large doses during
the intermission it lessened the severity, and apparently
sometimes prevented the relapses. Arsenic was useless,
but a combination of corrosive sublimate in tincture
cinchona has not been tried. Of course the enormous
development of the protooncocytes in the blood during the
paroxysms, and their disappearance during the intermis-
sion, suggested the use of parasiticides; but the sulphites
failed and the preparations of chlorine. The mineral
acids deserve attention, and turpentine, iodide, and
bromine.

The history of the Ephemera, a genus of insects of the
order Neuroptera, deserves a little attention here, merely
as corroborative and suggestive. Linnaeus gave the name
Ephemera to these insects because they appear in their
complete or winged form only for a day, though in the
larva and nymph states they are said to live beneath
water and elsewhere perhaps for two or three years.
Appearing above the water and in the air, they provide
for the continuance of their race, and then die. Though
but frail and delicate insects, they have been found in
certain districts in France covering the ground in such
enormous numbers as to be collected by cartloads for
manure. One form, the common white moth, or small
butterfly, the Ephemera albiennis, or white-winged, is
sometimes seen in such quantities by the banks of rivers
as to whiten the air and ground like drifting snow.
We do not wish any one to infer that these creatures
cause fever and ague, or relapsing, or any other form of
fever, but merely to point out a line of direction to
which the thoughts of scientists may be turned.

THE LOUISVILLE MEDICAL COLLEGES.

There appears to be no doubt that some very unseemly
practices have been going on in connection with the
medical colleges at Louisville, Ky.; and the Louisville
Medical College is said to be the chief offender. Docu-
ments are published showing that this institution began
last summer systematically to canvass for students, offer-
ing to many a reduction in the advertised price of tuition.

Such practices are certainly not reputable, and in the
end must hurt the reputation and standing of the college
which indulges in them. Institutions for medical instruc-
tion which have to beg and underbid for students, or
lobby for free scholarships, have survived their usefulness.

We hardly know what can be done, however. There
are plenty of medical students, the last census giving
over 10,000; but the colleges appear to increase as fast
as the students, and they must work for their share. We
can only urge it upon the medical profession that they
lend countenance and support only to such institutions
as show themselves conscious of the dignity of the pro-
fession, and of the deep responsibilities that fall upon
medical teachers at the present time.

News of the Week.

SUFFERINGS OF PHYSICIANS IN THE FLOODED DIS-
TRICTS.—We have received from Dr. D. B. Colton, of
Portsmouth, Ohio, a very graphic yet sad description of
the sufferings brought about by the flood at that place.

He writes that for nine days his office and residence
were under the water. Nearly all his medical books, the
accumulation of thirty years, were destroyed. His medi-
cines were ruined or washed away, his buggy wrecked,
and he had to swim his horse to high ground for safety.

During this time, he writes, "I was busy day and
night. I went from house to house in hurriedly
improvised boats, or on rafts, entering the second stories
through the windows, or climbing ladders and passing
over the roofs and descending through hatches. There
was much sickness and suffering, especially among the
children. Many women aborted from exposure and ter-
or, and there were a number of cases of eclampsia
among the parturient women. Many houses (whole
streets) are wrecked, or have been washed away down
the raging waters with all their contents. Our people are
impoeverished, and it will be a long time before they will
have anything to spare for the doctor." Six thousand of
them are fed to-day by the generous gifts of the noble
people throughout our land. God bless our benefactors,
and may none of them experience what we have just
gone through. If you know of any physicians in your
city who have duplicate copies of medical works or any-
thing in the line of physicians' supplies for which they
have no use, they will confer a favor if they will send
them to Portsmouth.''

We trust that some of our readers may be able to
furnish help in the way indicated. The Record will
co-operate in any efforts in this direction.

THREE CASES OF TYPHUS FEVER were found last
week in the city, and were removed to Riverside Hospi-

tal.

THE NEW YORK COUNTY MEDICAL SOCIETY.—The
Planet has shed the rays of its effulgent and penetrating
criticism upon the New York County Medical Society.
It is stated that the meetings are small, the papers poor,
and the discussions "put up" by specialists. On the
contrary, the meetings have never been larger, the papers
better, or the society more active and useful. Every
one who wishes to discuss a paper has abundant oppor-
tunity to do. We venture thus upon the painful duty
of contradicting our reflective contemporary, because its
comments will doubtless be industriously copied and
circulated by the same generous spirits which copied the
misstatements in the Ephemera about the County So-
ciety.
Foot-and-Mouth Disease prevails in Kansas, and a district thirty-five miles in area has been put in quarantine.

Animal Quarantine.—Our Government legislates in behalf of its cattle very easily. The House of Representatives has passed a bill empowering the President, in case of prevalence of contagious or infectious diseases among domestic animals in any State or Territory, to declare such State or Territory in quarantine, provided the Commissioner of Agriculture declare such disease dangerous to the animal industries of the nation, and the State or Territory fails to make provisions for its extirpation.

The Sixth Annual Meeting of the Sanitary Council of the Mississippi Valley will be held in the city of Memphis, Tenn., on Wednesday, March 19, 1884.

The Kentucky State Medical Society meets this year at Bowling Green, on June 3d, instead of May 7th, as first announced.

The Louisiana State Medical Society meets this year at Baton Rouge, May 21st. Dr. J. P. Davidson is president, and is making special efforts to have a large meeting. There is need of a greater interest in State societies on the part of some of our Southern States.

The Medical Department of the Arkansas Industrial University held its commencement exercises at Little Rock, on March 3d, and graduated a class of thirteen.

The Baltimore College of Physicians and Surgeons held its annual commencement on March 4th, and conferred diplomas upon one hundred and twenty-seven graduates.

The Baltimore Medical College held its annual commencement on March 6th, and conferred diplomas upon thirteen graduates. This college, we regret to learn, finds itself obliged to give up its long term of seven and a half months for a shorter one of five months. It gives a spring course, which is not, we presume, obligatory.

The St. Joseph Medical College held its seventh annual commencement on February 21st, at St. Joseph, Mo., graduating a class of six. Out of eleven who applied for degrees, five were "plucked."

The Missouri Medical College held its annual commencement on March 4th, graduating one hundred and two students.

The St. Louis College of Physicians and Surgeons held its annual commencement on March 4th, graduating twenty-eight.

The St. Louis Medical College held its annual commencement on March 5th, graduating thirty-four.

The Meharry Medical College for negroes, at Nashville, has just graduated a class of eight.

Albany Medical College.—On March 5th the alumni day and commencement of the Albany Medical College were celebrated. The alumni meeting was held in the afternoon, Dr. F. S. Greene acting president.

An address of welcome was made by Dr. Maurice Perkins; eulogies upon the late Dr. Mosher were then delivered. The prize of $300, offered by Dr. Albert Van Derveer for the best essay on Colles' fracture, was awarded to Dr. Clinton B. Herrick, of Troy. Dr. Horace T. Hanks, of New York, was elected president of the Association for the ensuing year. The commencement exercises were held in the evening, when a class of forty-three was graduated, with appropriate ceremonies.

The Medical Department of the University of New York held its annual commencement on the evening of March 11th, at the Academy of Music. Dr. John Hall, Chancellor of the University, presiding. Degrees were conferred upon one hundred and sixty-four graduates. The Mott Memorial Gold Medal, and various Faculty Prizes, were awarded. The valedictory address was delivered by Dr. F. K. Perkins.
The address to the graduates was delivered by Hon. Chauncey M. Depew. Every professional man, he said, owed something to the community in which he lives. All the educational, humanitarian, social, and political work of the neighborhood had legitimate claims upon him. His advantages imposed upon him public activities, and, in a sense, leadership. The doctor's opportunities surpassed all others. He should be informed and interested in all public questions, the friend of good government, and the enemy of bad rulers. His personality was as potent as his medicine. If of right mind and character, he imparts to the sufferer something of his own vitality, breezy hopefulness, and contented cheerfulness. "The Lord deliver me," said the speaker, "in mine extremity, from a doctor so absorbed in his own greatness or vanity that he cannot see me, the doctor who has a hobby and rides it roughshod over my aching bones, or the doctor whose breath is steeped in tobacco and whiskey. An eminent physician once gave as an axiom that the secret of longevity was a clear conscience and good digestion. The secret of becoming an eminent physician is devotion to your profession and cleanly life and conversation."

The Medical College of Ohio held its annual commencement on March 7th. At a subsequent meeting of the alumni, Dr. Sulton, president, delivered an address upon "Epidemics in Southeastern Indiana."

The Medical Department of the University of Louisville held its annual commencement on February 28th, graduating a class of seventy.

The Nashville Medical College held its annual commencement on February 26th, graduating a class of sixty-two.

Rush Medical College had its annual commencement on February 19th, graduating one hundred and sixty-eight students. According to the Weekly Medical Review, the hospital now in course of erection adjacent to Rush College, and which has been up to this time carried forward by the College, has been transferred to an association of Presbyterians, and will shortly be formally turned over to their control. The association will complete the building, and it will be known as the Presbyterian Hospital of Chicago.
MEETING OF THE GERMAN CONGRESS OF INTERNAL MEDICINE.—The third German Medical Congress will be held in Berlin, under the presidency of Professor Frensch, from April 21st to 24th. The following subjects have been selected for discussion. First day: Genuine Pneumonia, its anatomy, pathology, symptoms, and treatment (reporters, Dr. Jürgensen, of Tubingen, and Dr. A. Fränkel, of Berlin. Second day: Poliomyelitis and Neuritis (reporters, Dr. Leyden, of Berlin, and Dr. Schultz, of Heidelberg). Third day: Nervous Dyspepsia (reporters, Dr. Leube, of Erlangen, and Dr. Ewald, of Berlin). The following contributions have also been promised: Dr. Hermann Weber, of London, on the Hygiene of Schools in England, with special reference to infectious diseases; Dr. Rosenthal, of Erlangen, on Reflexes; Dr. Goltz, of Strassburg, on the Localization of the Functions of the Cerebrum; Dr. Pfeiffer, of Weimar, on Vaccination; Dr. Seagén, of Carlsbad, on Diabetes; Dr. Rosbach, of Jena, the Report of the Commission on the Treatment of Infectious Diseases, and on a New Therapeutic Action of Naphthalin.

THE PRESIDENCY OF THE NEW YORK STATE MEDICAL "ASSOCIATION."—We have received many inquiries and protests regarding the position of the president of the State Medical "Association," Dr. Didama, of Syracuse. There appears to be the most authentic evidence that he has regularly consulted with homoeopaths. This, we believe, he does not even deny. If it is so, it makes his election to the presidency of an association whose shibboleth is "no consultations with homoeopaths," a farcical performance. It also places the society in a very awkward position. We trust that a satisfactory explanation can be made. It is enough that the profession in the State be divided, without being made ridiculous.

THE THIRTEENTH ANNUAL CONGRESS OF GERMAN SURGEONS meets at Berlin, April 13 to 19, 1884, under the presidency of Professor von Langenbeck. Among the subjects to be discussed are the following: The Physiological Relations Between the Spleen and the Thyroid Glands; The Treatment of Paraplegia from Pott's Disease; The Ferment-intoxication from Blood-cysts; Massage.

KAIRIN is given subcutaneously by Queirolo, who finds that by this means less amounts can be given, and at rarer intervals.

THE TREATMENT OF RICKETS WITH SMALL DOSES OF PHOSPHORUS is strongly advised by Kassowitz, of Vienna.

Dr. P. Wesley Young died, on March 8th, at his home in Granville County, N. C. He was fifty-three years of age, and one of the most prominent physicians and surgeons in North Carolina. During the war Dr. Young served as a surgeon in the Confederate army.

THE NEW SURGEON-GENERAL OF THE NAVY.—The profession will learn with regret that Dr. Wales, who served so efficiently as Surgeon-General of the Navy, has not been reappointed. During his administration the naval medical service began to take a more important position than ever before in scientific, and especially in preventive, medicine. Dr. Wales' successor, however, Dr. Francis M. Gunnell, has an excellent reputation, and there is no reason to suppose that the department under his care will suffer any decline. Dr. Gunnell is a native of Washington, and an alumnus of Georgetown University and of the Columbian University, Washington. He has served in the medical corps thirty-five years, and been at sea nearly seventeen years.

THE JOHN HOPKINS HOSPITAL.—Already $211,000.36 has been spent upon this hospital, and it is estimated that $400,000 will be required for its completion. It is expected that it will be open before October, 1886.

DR. W. T. BELFIELD has been appointed Lecturer on Surgery in Rush Medical College.

THE STATE BOARD OF HEALTH—SUCCESSOR TO DR. ELISHA HARRIS.—The New York State Board of Health held a meeting on March 12th, and heard a report by Professor Chandler upon Water-gas. Professor Chandler said that practically it was no more poisonous than coal-gas, though it would kill people a little sooner. It was heavier than coal-gas, but was lighter than air, and had a perceptible odor.

Dr. Alfred L. Carroll, of West New Brighton, was elected Secretary in place of the late Dr. Harris. The Board is trying to secure the passage of a bill voting $20,000 to prevent adulterations in food and drugs.

MEDICAL BERLIN.—At the meeting of the Berlin Medical Society, January 30, 1884, Dr. Worms exhibited a case of Emphysema of the Skin. A young girl of seven had suffered for several years from a bronchial catarrh, and was in a feeble condition. She was finally taken with severe attacks of coughing and vomiting. This was followed by pains in the neck and chest, and finally by a large emphysematous swelling of these parts. Dr. Worms believed that an air-lobule had burst, the air had escaped along the hilus of the lungs to the mediastinum and deep cellular tissue of the neck. The Society then resumed the discussion of matters pertaining to medical politics.

MEDICAL PARIS.—At the session of the Académie de Médecine, February 19th, M. Brouardel read for M. Ferré, of Bordeaux, a note upon the microscopic examination of vaccine lymph. The most remarkable element observed was a microbe somewhat like that described by M. Jolget. It was from one to three micromillimetres in diameter. They appear to be convex upon the upper surface, concave on the lower, from which latter there are two processes. These organisms have a rotary movement. M. Pinard related the history of a successful case of vaginotomy for extra-uterine pregnancy. The fetus, which had been dead for a month and a half, was successfully extracted by means of an incision made in the posterior cul-de-sac of the vagina, to which the fetal cyst was adherent.

The Society then continued its discussion of the lunacy laws. In this connection we add a criticism upon the Académie de Médecine made by the correspondent of The Lancet: "The Academy," he says, "seems to be growing less and less interesting, if one may judge from the small number of members who have been attending it for some time past. At the meeting of last
week there were so few present (scarcely a dozen) as to call forth the displeasure of M. Alphonse Guérin, the President, who expressed himself to that effect, and actually requested the reporters present to notice the fact in their respective journals. It has been remarked that it is only on election days that the Academy shows a pretty good muster, and that the absentees are generally to be found among the younger members. It must, however, be admitted that the meetings of the Academy, or rather the discussions that have taken place in it lately, are anything but interesting; little is to be learned from them, as the members go over ground that has already been traversed several times, old subjects merely being introduced under a new garb, and frequently left as before—that is, without any solution of the question submitted for discussion."

MEDICAL VIENNA.—The Royal Society of Physicians occupied the usual time of its session, on February 8th, by visiting the auditorium of Professor Stricker's laboratory, in order to witness a demonstration of the electric light in microscopical demonstration. The current could be used for lighting the hall, or could be turned into the microscope camera. The microscopical image of the mesentery of a living frog was thrown upon the screen, and the circulation of blood shown with great distinctness. By the same means Stricker then demonstrated the structure of tendon; and Kundrat showed some pathological specimens.

THE SIMS MEMORIAL FUND.

To the Medical Profession and Others throughout the World:

The great achievements of Dr. J. Marion Sims call for some more lasting testimonial than obituary and eulogies. To him medical science is indebted for much brilliant and original work, especially in gynecological surgery. Those who have been benefited by his teachings and new operations, and such as have had the direct advantage of his personal skill are among the first to recognize and acknowledge this debt.

To him is due the honor of giving the first strong impulse to the study of gynecological surgery in America.

It is believed that the medical profession everywhere, the vast number of women who owe their relief from suffering directly to him, and those who realize the benefits he first made possible, will gladly unite to honor the man through whose original and inventive genius such blessings have been conferred upon humanity.

At the suggestion of many friends, therefore, the subjoined committee has been organized, and it is proposed that a suitable monument be erected to his memory in the city of New York.

To this end the active co-operation of the medical profession and the many other friends of Dr. Sims throughout the world is respectfully solicited. Contributions of one dollar and upward may be forwarded to the journal which has been constituted the treasury of this fund—The Medical Record, New York.

THE MEDICAL RECORD.

March 15, 1884.] THE MEDICAL RECORD.

Reviews and Notices of Books.

There is something in this volume that distinguishes it from most of the works written for the instruction of the laity, viz., originality of research. One of the authors is a surgeon and a laryngologist of some prominence, while the other is a lecturer on the physiology of voice production. Both have previously contributed to the literature of the vocal apparatus, and they have now joined forces in the preparation of this work.

The first thing that strikes the reviewer is the success that the authors have had in obtaining photographic reproductions of the interior of the larynx during the production of various notes. They are truly remarkable and worthy of the highest praise. The difficulties of the task cannot be underestimated.

The other illustrations embodied in the work are very well executed wood-cuts and add to the interest of the volume; but they contain little that has not been equally well presented by others. Some of them are adaptations of illustrations already well known.

The text of the work covers the anatomy and physiology of the chest and larynx, and the laws of sound with some detail. Forty pages are subsequently devoted to the laryngoscope and its uses; about fifty to the hygiene of the vocal apparatus; sixty to the cultivation of the singer, and twenty-five to directions regarding the daily life of the singer; twenty to the various ailments of the voice; and about fifteen to defects of speech.

This volume is destined to become popular among those who either have, or are anxious to have, a musical voice and with public speakers. Its style is lucid and comparatively free from technical terms, in which respect it is to be commended. The publishers have issued the work in an attractive form.

The volume before us varies in a manner from the general run of similar works, as regards the method in which the several portions of the text are presented to the reader. The author's design has been to give clearly and concisely a simple description of the elements and their principal compounds, together with the chemical principles involved in some of the most important branches of manufacture. With this object in view, he has permitted as few technical terms as possible to be employed, more particularly at the commencement, thus affording the student of chemistry the comparatively rare opportunity of passing almost unconsciously into the application of its science, and, with more comprehension of the details than is usual, without having first to master that branch of the science which treats of the various terms employed, and which, moreover, he cannot well appreciate at the onset. A great assistance in this direction is also afforded by numerous descriptions throughout, and in most instances accompanied by woodcuts, which in the book on which the author has considered most useful in delineating his lectures, and thus fixing the attention of the student, as well as assisting those who wish to make similar experiments for their own instruction or for the benefit of a class.

As a rule, English weights and measures and the Fahrenheit thermometric degrees are employed. The various calculations are also given in the simplest arithmetical form. The table of atomic weights is arranged so as to indicate the quivalence of the elementary bodies. Special attention is also devoted to metallurgy and other branches of applied chemistry, which will prove of rare service to those who are devoted to manufacture. The content of contents deserves especial mention. This has been made in the form of a key, which will serve comparatively the purpose of a quiz, by means of which the student may examine himself upon each or any portion of the book. The index, which is essentially of great importance in a work of this kind, is arranged with much satisfaction, besides being a dictionary of the most important formulae. No one, more especially the student, can fail to appreciate the assistance which the work will afford; and for those who desire merely a general knowledge of the subject, without its several details, the book is highly commendable, inasmuch as all matter which would be of less importance to them is presented throughout in smaller type.

SURGICALLY APPLIED ANATOMY. By Frederick Treves, F.R.C.S., Assistant Surgeon to, and Senior Demonstrator of Anatomy at the London Hospital, etc. Illustrated with sixty-one engravings. Philadelphia: H. C. Lea's Son & Co.

The author of this manual has intended it chiefly for the benefit of students preparing for their final examinations in surgery, although he hopes that younger students may find it service in rendering not only their surgery but also their anatomy more intelligently and more easily comprehended. The work will also be found valuable to the general practitioner as a book of ready reference. The application of surgery to the several details of anatomy and the actual bearings which anatomy has upon the effects of disease are presented in a simple and concise manner for which the author deserves great credit. The entire general subject of anatomy is gone over, as a rule, however, avoiding all detailed description; e.g., in hernia the accounts of the regions concerned are omitted, the reader being referred to the systematic treatises, and the author dealing only with the bearings of anatomy of the parts upon the circumstances of practice. Also, for a similar reason, all those parts of the surgery of the arteries which deal with ligatures, collateral circulation, abnormalities, etc., are likewise omitted. In general, the book is thorough in its plan, easy of comprehension, and is well worthy of recommendation.

HEALTH IN THE HOUSEHOLD; OR, HYGIENIC COOKERY. By Susan W. Dodds, M.D. New York: Fowler & Wells, 1884.

Considered as a scientific contribution this book, which is simply a rapid rehash of vegetarianism, is dear at any price; regarded in the same light as that now classical work, "English as She is Spoke," or, in other words, as a pure and typical example of a "joke in sober earnest," we can cordially endorse it as a capital investment. By those misguided persons who have been led astray by the unnatural doctrines of Dalton, Flint, and other. dissolve physiologists, and who are hopelessly steeped in the futilities of the fleshpots, we who are earnestly striving upon a diet of the whitest bread they can bribe their baker to furnish, and to whom the old saw about the "buttered side down" is still a painful reality; who habitually indulge in the deepest potations of water during their meals and shamelessly touch, taste, and handle the unclean thing at a temperature less than 112° F.; to whom lard and total depravity are synonymous terms, and who revel in
the wildest orgies of the ham-and-eggs habit, the glowing effort of our ardent author will be received with a ribald merriment symptomatic of their debauched intellects. We do not doubt, however, that those who are wont to sup on the horror of the advertising columns of our alleged religious contemporaries will be quick to hail this hygienic missionary as the worthy successor of that apostle of sweetness and light in the realms of evangelical physiology, the late lamented Lydia.

A TREATISE ON PHARMACY: Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmacist, containing the Official and many Unofficial Formulas, and numerous Extemporaneous Prescriptions. By EDWARD PARRISH, Late Professor of Therapeutics and Practice of Pharmacy in the Philadelphia College of Pharmacy, etc. Fifth Edition, enlarged and thoroughly revised, by THOMAS S. WIGAND. With two hundred and fifty-six illustrations. 8vo, pp. 1,090. Philadelphia: H. C. Lea's Son & Co. 1884.

The new, fifth, edition of Mr. Parrish's standard work, the editor states in his preface, has been rendered an imperative necessity, not only by the late revision of the U. S. Pharmacopeia, but also by the great advance in chemical and pharmaceutical science within the last ten years. In the present volume, while a whole part has been made of condensation, yet the many necessary changes, which have greatly increased the labor of the editor, have also added materially to the size of the book. The new preparations of the Pharmacopeia have been embodied in the work, together with its tests for chemical and official compounds, and its system of parts by weight instead of definite quantities. The entire chemical section has been rearranged, and the subjects both of qualitative and quantitative analysis are presented as completely as possible. All general pharmaceutical and chemical processes have been arranged separately, thus affording ready reference and avoiding repetition. The syllabi, which in previous editions were deemed so essential a feature, have been retained. On these Professor Maisch has bestowed much care, and while many of them have been rewritten new ones have also been added. In addition, all new remedies of value have been introduced in the work, and in the chapter on Elixirs many new popular formulae are noticed. The editor has certainly completed his task with much credit, and there can be no doubt of the fair appreciation with which the present edition will be received.

We are glad to notice that Mr. Milton's carefully written and thoroughly deserving work on this important and perplexing subject has reached its fifth edition. The reader is at once struck with the earnestness as well as the scientific acumen of the author, who gives us the carefully sifted results of a vast amount of research in language guilelessly elegant, pointed and forcible. His earnestness, however, is never accentuated by prejudice; he strictly preserves the judicial character throughout. His polished style and rhetorical vigor have not tempted him from a direct and simple presentation of his subject. On the contrary, the book is thoughtful, energetic, business-like, and practical throughout. "My aim," says the author in the preface "was, as far as possible, to separate clearly what might be looked on as established from what was doubtful, and not merely to prove every assertion, but to place it on such a basis that it could not be disproved. Nothing has been recommended by myself in this work but what has stood the brunt of critical examination, for that I rate neither low, but of special observation." A rather difficult job, this; yet no one can read the book without admitting that our author, while dodging nothing and departing in nowise from the scheme laid down by himself at the start, has certainly succeeded remarkably well. There are few subjects in medical literature more entangled in tradition and stained with the most extravagant empiricism, than this one of the treatment of gonorrhoea. Very cunningly, the author, in his treatment of branch diseases, devotes the whole of his voluminous efforts to devoted to its discussion; and the natural, logical, masterly, and often adroit way in which he evolves order out of chaos is deserving of the highest praise. As a well-knit philosophical treatise the book is a model. As a hand-book for the busy practitioner it is a most valuable and reliable acquisition to a literature thoroughly filled with uncertainties; with the achievement of a thoroughly digested results of personal investigation according to modern scientific methods, it will be not merely suggestive, but indispensable to the specialist.

The book before us provides for all the ordinary records generally kept by the physician, as required by the various State laws, together with a full history of the pregnancy and the events pertaining to it. In addition, it embodies full medical statistics, viz.: The diseases and the tendencies to diseases in the father and the mother, their habits, etc., as well as the future medical history of the child, so that it may be impossible for the book to claim all that it claims to be, a complete obstetric record, and is far more desirable than the usual blanks offered to the profession.

TRANSACTIONS OF THE MINNESOTA STATE MEDICAL SOCIETY. 1883.

We are in receipt of the volume for 1883 of the "Transactions of the Minnesota State Medical Society," which held its annual meeting June 19th. The address of welcome was delivered by Dr. McMurdy. A resolution was adopted, urging upon Congress the necessity of making an appropriation sufficient to provide a fire-proof building, suitable to accommodate the collections of the Army Medical Library and Museum. The president, Dr. Milward, delivered the customary address, dwelling particularly upon micro-organisms and their part played in the animal and vegetable kingdoms. Following this the usual essays were presented, many of which were of marked value.

A PRACTICAL TREATISE ON SURGICAL DIAGNOSIS, designed as a Manual for Practitioners and Students in Medicine. By AMBROSE L. RANNEY, A.M., M.D., Professor of Practical Anatomy in New York Post-Graduate Medical School, etc., etc. Third edition, thoroughly revised, enlarged, and profusely illustrated. 8vo, pp. 608. New York: Wm. Wood & Co. 1884.

One of the noticeable features in the new edition of Professor Ranney's "Diagnosis" is the plentiful supply of descriptive text in connection with his plan of classification. This is a great improvement and tends to make the book more directly available for the student who does not already appreciate the force and significance of certain symptoms. Dr. Ranney has laid this essential ground-work very well and has enhanced the value of his general work accordingly. In a work of this sort too much cannot be done to bring out the principal points of a subject within a proper and comprehensible compass. In this respect our author has succeeded admirably. Especially is this true with his masterly summary of the diseases of the brain and nervous system. We have not seen in any work so much on this subject in such a small space. But we do not desire to make any criticism which would prove interesting and instructive throughout, and as such we continue to commend it to the earnest student and the progressive practitioner.
NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 6, 1884.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE

CHAIR.

THE PRESIDENT presented a letter received from Dr. Horace P. Farnham, containing his check for $5,000, donated to the Academy.

On motion by Dr. Hubbard the Academy voted to make DR. HORACE P. FARNHAM A BENEFACCTOR, and on further motion the thanks of the Academy were extended to Dr. Farnham for his magnanimous donation.

The Treasurer of the Board of Trustees, Dr. F. A. Castle, received the check, and then gave a brief summary of the financial condition of the Academy, in which it was stated that since the last annual meeting he had received donations to the amount of nearly $1,700. He hoped to be able to pay $2,000 on the mortgage on April 1st, next, and thus reduce it to $5,000.

On motion by Dr. Hubbard, the Treasurer of the Board of Trustees was empowered to pay $2,000 on the mortgage on April 1st next, provided that amount be in the treasury.

The Council reported in favor of publishing a volume of "Transactions." The report was adopted.

DR. GEORGE B. FOWLER then read a paper ON THE DETECTION OF ALBUMEN IN URINE, WITH A REVIEW OF THE METHODS RECENTLY ADVANCED.

After alluding to the fact that the albumen which appears in the urine exists in the blood in the proportion of about nine per cent., the so-called native albumen, or serum albumen, the author of the paper demonstrated how it was precipitated by heat, nitric acid, picric acid, sodium tungstate, potash-mercuric iodide solutions, etc., Heat will detect two-tenths per cent. (0.2) of albumen. It is necessary that the urine be nearly neutral, to make it most available, because an excess of either an acid or alkali will, if albumen is present, convert it into a form which heat dissolves. Always apply heat before adding any acid, and if the fluid is entirely coagulated it contains more than one-tenth per cent. albumen.

Nitric acid will detect one-tenth per cent. (0.1) of albumen. Dr. Fowler then alluded to the most approved methods of using nitric acid, such as Heller's, allowing the acid to trickle down the side of the test-tube, etc.

Picric acid will detect one-tenth per cent. of albumen (0.1). This test seems to have excited more discussion than any of the others. It has certain drawbacks, however, as the change in color which it produces in the urine, staining the fingers, etc.

The acidulated brine of Dr. Robarts was discarded. The sodium tungstate test proposed by Dr. Oliver was applied, and the use of Dr. Oliver's compound test-papers demonstrated. This test will detect one-tenth per cent. of albumen (0.1).

The most delicate test was the potash-mercuric iodide solution, which detected one one-hundredth per cent. (0.01) of albumen.

Most of these newest tests will give a reaction with other matters, such as the peptones, quinine, etc., and this fact constitutes a serious objection to their use. Dr. Fowler believed in peptonuria, because he had seen it. The objection to these tests on the score of reaction to other substances than albumen he thought was readily overcome by a simple test for peptones, and by inquiry as to whether or not quinine had been taken within a certain number of hours.

He regarded the slightest trace of albumen as of sufficient importance to deserve careful watching, and therefore the real practical value of these delicate tests, at least until it had been settled what the real significance of a trace of albumen in the urine was.

THE PRESIDENT thought it important to know, if possible, exactly what the slight traces of albumen in the urine meant; whether or not they indicated the existence of acute inflammation, or whether or not they were found in the urine of healthy persons, or indicated temporary or permanent kidney lesions.

DR. E. D. HUDSON, JR., said he still held to the older and more simple tests. He thought that the presence of albumen by the ordinary tests should lead to careful microscopic examination of the urine. For ordinary clinical observations, heat and nitric acid were sufficiently accurate, if used with the care and precaution which should always be exercised in their application. A method which he had found exceedingly satisfactory was to raise a few drops of urine in a perfectly clean pipette and then draw additionally in a few drops of nitric acid, when, if albumen was present, the delicate cloud could be seen where the two fluids unite.

DR. GASPAR GRISWOLD thought that the subject should be studied from two standpoints. First the chemical, which of course, would decide that that test was the best which detected the smallest quantity of albumen. Second, the clinical, and under this head that test should be regarded as best which contained the least number of sources of error, and thus lessen the chances of making mistakes. He spoke at some length with reference to the liability to error in the use of the recent more delicate tests, and had become convinced that, with proper precautions, heat and nitric acid would yield as delicate results as could be obtained by more complicated methods. One essential to a careful examination was a clear urine, which could be obtained by filtering. Then his method of using heat and nitric acid was to take two test-tubes, one containing urine the other an equal quantity of acid, and after boiling one, mix the two fluids slowly, which was done by pouring that of one test-tube into the other.

DR. C. A. DOREMUS spoke with reference to the importance of cleanliness in making all these clinical tests. He suggested the use of meta-phosphoric acid as possibly a more delicate test than any yet employed.

DR. J. P. MUNN, spoke especially of the importance of a properly shaded light for detecting delicate clouds of albumen. His method was to draw down the window shade fully, sweep it to and fro as the window, perhaps six inches, and then with a black background upon the wall immediately below the window the light would so strike the test-tube, when held in front of the background, that the most delicate precipitate could be readily seen.

DR. E. A. MAXWELL had used picric acid for two years with very satisfactory results. He had used a saturated solution and adopted Heller's method reversed. He had failed to find peptonuria, and also had regarded the presence of a small quantity of albumen in the urine as of not much significance.

DR. FOWLER, in closing the discussion, said we should not rely upon one test, and further that he believed we were not yet prepared to say how small a quantity of albumen in the urine had no clinical importance.

The Academy then adjourned.

MIXED COLLEGE FACULTIES.—The Kansas City City Hospital College of Medicine has a full faculty of regular physicians, and in addition has a chair on homoeopathy. Because of this attachment, the Missouri State Board of Health has refused recognition to its graduates. The college has, says the Medical Age, accordingly, applied to the Supreme Court for a mandamus. The State Board to show cause why it should decline to register its diplomas. The action of the Supreme Court is awaited with interest.
NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, February 27, 1884.

JOHN A. WYETH, M.D., President, pro tem., in the Chair.

DR. W. P. NORTHROP presented the following

REPORT FROM THE COMMITTEE ON MICROSCOPY

concerning specimens presented by Dr. A. JACOBI at the last meeting held February 13, 1884: "Lungs: Diffuse interstitial pneumonia, infiltration of the alveolar walls, alveoli generally filled with moderate amount of fibrin with few swollen epithelial cells and pus cells. Liver: marked accumulation of small spheroidal cells about the peripheral veins; liver cells show moderate fatty infiltration. Spleen: Malpighian bodies swollen, congestion, slight increase in connective tissue stroma. Kidneys: cells of convoluted tubules slightly swollen and granular."

DR. F. N. OTIS, on behalf of a candidate, presented a specimen of

CANCER OF THE CESOPHAGUS.

DR. GEORGE A. DIXON presented a specimen, accompanied by the following history, furnished by Dr. G. G. WEISS, House Physician at Charity Hospital.

PRIMARY CANCER INVOLVING THE HEAD OF THE PANCREAS WITH SECONDARY DEPOSITS IN THE LIVER.

J. S——, fifty-four years of age, laborer, and a native of Ireland, was admitted into Charity Hospital, November 27, 1883. Family history good. The patient was well up to two years ago, when he had an attack of intermittent fever, which yielded readily to quinine. He resumed work in a week. In September, 1883, while lifting a heavy weight, he strained himself across the abdomen. Two weeks later he began to be troubled with pain in the right hypogastric and epigastric regions, which was dull in character and increased by pressure. Five weeks after the injury he vomited blood, quantity not known. The patient gradually grew more severe, and on account of this he came to the hospital. He said he had lost in weight thirty pounds since the injury. The patient has been a moderate drinker, denies syphilis. On admission the skin and conjunctive were of a dirty yellowish color; mucus membranes pale. Patient much emaciated, large abdomen, and examination of the lungs revealed emphysema and bronchitis. Heart sounds weak, no murmur detected. There was marked tenderness over the liver, which was of about the normal size. The gall-bladder could not be made out. The spleen was not enlarged. The intestines contained a good deal of gas. The urine, dark-colored, sp. gr. 1.016, contained bile, no albumen, and microscopic examination was negative.

The patient was ordered to remain in bed, and he received tonic treatment with hot fomentations over the abdomen.

December 7th.—Has suffered less from pain and desires to get up. Bowels regular, stools light-colored.

December 14th.—The pain has increased over the liver. The jaundice is more intense, the bowels are very sluggish.

December 20th.—Patient had a severe attack of epistaxis.

On December 22d he was given calomel, grs. x., sodic bicarb., 3 ss. at night, and Rochelle salts in the morning. The bowels moved freely, stools of a dark brown color. The patient continued to improve.

January 5th.—During the past two weeks the patient has failed very much, has vomited frequently and copiously and the matter ejected is of a grayish-black color and quite fluid.

January 9, 1884.—The patient is delirious and vomits frequently; the stools are grayish in color.

The patient died at 6.30 P.M., January 12, 1884.

Autopsy, twenty-four hours after death.—Brain normal. Lungs emphysematous. Heart weighed twelve ounces; hypertrophy and dilatation of left ventricle, right ventricle dilated; valves normal. Spleen weighed four ounces, congested. Kidneys: capsule non-adherent, surface pale and slightly fatty. The mucous membrane of stomach is pale and thickened in places; in the mucous membrane of duodenum deeply pigmented. The orifice of the common bile-duct is three inches below the pylorus. Just below the opening of the common duct there is an irregularly shaped ulcerated surface, involving the mucous membrane of the duodenum. This surface measures 1 1/2 inch vertically by 2 inches transversely, and on the other side of there is hereby mucous membrane. Corresponding to this space is a tumor which occupies the position of the head of the pancreas. The head of the pancreas has been invaded by a large cancerous mass of the scharir variety. This mass surrounds the intestine and measures about 2 1/2 inches in thickness. It is adherent to the aorta behind, and projecting from the left side is the body of the gland, measuring 5 inches in length, which is normal in structure. The liver is normal in size. On its anterior and posterior surfaces are seen a few small yellowish nodules, which are slightly elevated, and have a hard feel. On section through the organ these same nodules are seen here and there. Microscopical examination shows scharir variety of carcinoma. The hepatic lobules are distinct, the centres being depressed and pigmented, and their periphery anaemic and containing a large quantity of fat. The hepatic, cystic, and common ducts are enlarged and perivious. At autopsy bile could be easily pressed into the intestine. The gall-bladder contained eight ounces of bile, and was of the same size as before admission.

On the 13th of December, Dr. Dixon gave the history of a case which was under his observation while an intern at Bellevue Hospital.

CYSTIC DEGENERATION OF THE PANCREAS.
